Secretary.
SAMUEL W. ABBOTT, M.D.

Engineer.
X. H. GOODNOUGH, C.E.

GENERAL REPORT.

This twenty-eighth annual report of the State Board of Health contains a statement of the general work of the Board for the year ending Sept. 30, 1896, and of that which relates to water supply and sewerage for the calendar year 1896.

The first portion, the general report, paged in Roman numerals, includes a condensed statement of the work done under the statutes which define the work of the Board.

To this is appended the reports, in brief, which the Board has already presented to the Legislature upon the sewerage of Salem and Peabody and the improvement of the Neponset valley, also the joint report of the Board with the Metropolitan Park Commission on the improvement of the Charles River.

The second part of the report, paged in Arabic figures, contains the fuller details of the work of the Board, under the acts relating to water supply and sewerage, food and drug inspection, reporting of infectious diseases, and such papers upon special topics as the Board has deemed it desirable to publish. In the recent reports of the Board it has been customary to present a condensed annual statement of the vital statistics of the State. In the present report this statement is presented, with much greater fulness of detail, in the form of a forty-year summary, in which comparative statistics are quite fully presented of the earlier and later portions of the period (1856–95). This summary is presented in compliance with an increasing demand for information of this character.

The following members comprised the Board in 1896: -

HENRY P. WALCOTT, Chairman.

FRANK W. DRAPER. HIRAM F. MILLS. JAMES W. HULL. GERARD C. TOBEY. CHARLES H. PORTER. JULIAN A. MEAD.

No changes have taken place in the membership of the Board during the year.

INFECTIOUS DISEASES.

The group of diseases known as infectious, including tuberculosis, has diminished with a considerable degree of uniformity during the past half century in its incidence upon the population. Exceptions occur in the case of single years, as well as in the case of separate diseases or causes of death, but as a general rule the death-rate from such diseases appears to be steadily decreasing. This is more apparent when five-year periods are compared than when the comparison is applied to single years.

For example, the combined death-rate from small-pox, measles, scarlet-fever, diphtheria and croup, typhoid fever, cholera infantum, consumption, whooping-cough, dysentery and child-birth * was as follows for the forty years (1856-95), in five-year periods:—

Death-rate per 10,000 living from Certain Diseases.

| 1856-60, | | | 81.7 | 1876-80, | | | 73.1 |
|----------|--|--|------|----------|--|--|------|
| 1861-65, | | | 93.0 | 1881–85, | | | 65.1 |
| 1866-70, | | | 74.8 | 1886–90, | | | 56.8 |
| 1870-75, | | | 84.9 | 1891–95, | | | 50.5 |

By the foregoing figures it will be seen that the decrease has been much more uniform in the second twenty years than it was in the first.

During the first twenty years the combined death-rate from these causes rose to more than 100 per 10,000 living in three years of the period (1863, 64 and 72), while in the second period at no time did it rise above 82.7 (in the first year, 1876) and fell to a minimum of 47.1 in 1895.

Small-pox.

Since the occurrence of the limited epidemic of small-pox of 1893 and 1894 there have been but very few cases reported in the State. The whole number of cases officially reported to the board in 1896 under the statute of 1883, chapter 138, was 5 and the details are as follows:—

^{*} The explanation of the different incidents of child-birth embraced in this term may be found on page 804.

Cases of Small-pox reported to the State Board of Health in 1896, under the Provisions of Chapter 138 of the Acts of 1883.

| No. | Date of Report. | Place of Occurrence. | Nationality. | Occupation. | Age. | Sex. | Previously Vaccinated. | Number of Scars. | Deaths. |

^{*} Vaccinated twenty years before.

A sister of No. 5 was a rag cutter in a paper mill.

Nos. 3, 4 and 5 occurred in places where paper mills using rags are located.

No. 1 was a cook employed among laborers on the Cambridge water works.

Cases of small-pox occurring in other parts of the United States were reported to the Board in 1896, under the provisions of an interstate agreement made at Toronto, Ontario, in 1886.

In February, 2 in Connecticut, 1 each in Michigan and the Provinces of Quebec and Ontario.

In March, 2 in Alabama, and 1 each in Kansas and Indiana.

In April, 11 in Alabama and 3 in Pennsylvania.

In May, 1 each in Indiana and Washington (State).

In June, 1 in New York.

In August, 1 in Washington.

In November, 1 each in Indiana and Ohio.

In December, 1 in Pennsylvania.

These 30 cases, together with the 5 in Massachusetts, making 35 in all, are all that were officially reported in 1896 in a population of about seventy million people.

In addition to the foregoing, notice was received from the quarantine station at New York of the arrival at that port of the steamers "Massilia," "Victoria" and "Patria" on February 7, April 27 and May 9 with cases of small-pox on board. These steamers all hailed from Naples, and had immigrants on board destined for Massachusetts cities and towns, and in each instance the boards of health of these cities were notified of the fact. It is not known that the disease was communicated to inhabitants in any of these cities.

[†] Vaccinated nine years before.

Typhoid Fever.

No disease or cause of death constitutes a better index or measure of the efficiency of sanitary work than typhoid fever. The number of deaths from this disease has diminished with considerable uniformity in proportion as public water supplies have been introduced in the cities and towns. A table and diagram in the portion of this report which is specially devoted to vital statistics illustrates this principle.

The returns for 1896 are not all in at the date of writing this, but sufficient information is at hand to show that the past year proves no exception to the rule. The notifications of infectious diseases which are constantly received at the office of the Board give evidence of the fact as well as the diminished requests for the assistance of the Board in the investigation of epidemics.

The principal epidemic of this character which occurred during the time embraced in this report was that of North Adams. This epidemic was reported to the State Board of Health by the board of health of North Adams late in September, 1895, and Professor Sedgwick was instructed to proceed to North Adams and to investigate the cause and aid the local board in its inquiries.

It appears from the table which is given on page xiv that North Adams has had a persistently high death-rate from typhoid fever for several years.

Professor Sedgwick found that considerable apprehension existed at North Adams with reference to the condition of the water supply, which is taken from certain reservoirs made by impounding the water of brooks in comparatively uninhabited regions, and from driven wells near the centre of the city.

Although the water of these wells is hard and comparatively impure it did not appear that they could be charged with causing the unusual prevalence of typhoid fever, since the distribution of the cases would not warrant this inference. Most of the cases in 1895 occurred in the western and northern sections of the city and especially in the valley along the watershed of the north branch of the Hoosac River.

The deaths registered in the four months of June, July, August and September in the five years 1891-95 were as follows: 1891, 3, 1892, 3, 1893, 5, 1894, 10 and 1895, 11.

The cases which occurred in 1895 did not appear simultaneously or in large numbers, as is common in epidemics due to infected milk

or infected water supplies, but were continued at intervals from the middle of July to October, a few being reported in each week.

Professor Sedgwick says: "The epidemic was of a slow, insidious character, as if slowly passing from person to person, and from house to house; and as has been stated, it was confined to one, and that an unsanitary section of the city."

It was recommended that an agent of the Board of Health should be detailed to give special attention to disinfection among the houses in this district where the fever existed.

Limited outbreaks were also reported as having occurred at the Mount Hermon School in Northfield, at the State Prison, and at Rowley, Mass., but the total number of such outbreaks has been much less than it has in previous years.

Five men were taken ill at the State Prison in October, and the secretary visited the prison and inspected its sanitary condition. The general condition of the buildings, cells, kitchen, hospital and other apartments appeared to be good. A sewer was being constructed in the grounds outside, upon which the convicts were at work, but none of those who were taken ill had worked upon this sewer.

The water supply is the water of Mystic Lake in Medford, occasionally alternating with water from the general, or Cochituate and Sudbury supply. The Mystic supplies the cities of Somerville, Everett and Chelsea. An inquiry of the health authorities of these cities showed that typhoid fever was not unusually prevalent among them at the time of the occurrence of the cases at the prison.

Attention was then turned to the milk supply, which was obtained from a contractor doing business in Charlestown, having a large business, and obtaining his milk from about one thousand dairies in Maine and southern New Hampshire. The milk came in each morning over the Western Division of the Boston & Maine Railroad, being collected at a station in southern New Hampshire.

The conditions prevailing at the milk distributing station at Charlestown were fairly good, and all the men connected with the work of distribution and present at the station appeared to be in good health and free from infection.

One man who had charge of the stable, opening out of the distributing room, was given a vacation September 8 and went away, but was soon after attacked with typhoid fever and went to hospital, where he was at the time of the inspection (October 22). This man

had no connection with the work of distributing or handling of the milk, and his illness was undoubtedly in the relation of effect and not of cause, since he and his family used the milk furnished by this contractor.

The supply furnished to the prison was forty cans four times a week, and these were not always from the same dairies, but so far as could be learned were from several dairies along the line of a railway extending from southern New Hampshire to Maine. It was deemed impracticable to continue the investigation in this direction.

Another limited epidemic, in which the total number of cases was only 7, was that of the Mount Hermon School, on the west bank of the Connecticut River in Northfield. An inspection of the school was made and advice given relative to its water supply and sewage disposal.

In the reports of the Board from 1890 to 1895, inclusive, a table has been published annually presenting the deaths and death-rates from typhoid fever for a series of years in the cities of the State, these cities being arranged in the order of their population. In the present report, page xiv, this table has been rearranged, the statistics relating to typhoid fever being presented in five-year groups, and in each period the cities are arranged in accordance with the intensity of their death-rates from typhoid fever. North Adams, which became a city in 1895, has been added to the list, making a total of thirty-two cities.

By means of this table the comparative rank of the different cities in each period and the rise or fall in the typhoid death-rate from one period to another are shown.

While the general improvement in the death-rate from typhoid fever, coincident with the introduction of better water supplies, is shown in the latter part of the report in the portion relating to vital statistics, it also appears in this table, where the conditions of certain cities are considered separately.

In some instances radical changes have taken place in the rank of cities, comparing early with late periods. Boston has maintained a position quite uniformly intermediate in the list, and usually slightly below that of the State. It would undoubtedly have been still lower were it not for its intimate connection with the surrounding territory and the presence of many hospitals, in which patients from other cities and towns are admitted for treatment. The manufacturing cities, Holyoke, Springfield, Chicopee, Lowell, Lawrence, Fall River and North Adams, have generally had high death-rates

throughout most of the time included in the table. On the other hand, the smaller residential cities, Waltham, Newton, Medford, Everett and Woburn, have usually been found near the foot of the list, with low typhoid death-rates.

Holyoke, which in the first three five-year periods was at the head of the list of high death-rates, has shown a decided improvement in the fourth and fifth periods.

Pittsfield, also, from a position above the mean, has dropped below the mean, and in the fifth period had the lowest death-rate from typhoid fever among the cities.

On the other hand, Newburyport has changed its position from a generally low rank to a position near the top of the list.

The death-rates in this table are annual death-rates per 10,000 of the living population. The population had increased, during the whole period indicated in the table, about 83 per cent. (comparing the mean population of the first five years with that of the last five).

Deaths and Death-rates per 10,000 Inhabitants from Typhoid Fever in Massachusetts Cities, 1871-95.

* North Adams not incorporated till 1878.

This comparison may be carried still further by an examination of the following table for the year 1896, which has been made up from the returns required by chapter 218 of the Acts of 1894. The figures in this table may differ slightly from those which are obtained from the Registration Report at a later date, but the difference is usually very small. It may also be noted that the results of a single year are not so conclusive as those of longer periods, and those of small cities are less conclusive than those of large ones, according to the usual principle of the limits of error.

Haverhill is found at the top of the list in this table for 1896. With regard to the high typhoid death-rate of Haverhill in 1896 reference may be made to Professor Sedgwick's report to the board of health of that city, quoted near the close of this volume, under the head of "Health of Towns."

Lynn in the last decade, 1886-95, maintained a record for typhoid fever mortality better than the average. In 1896 the death-rate of Lynn from typhoid fever is only the sixth from the top of the list.

On the other hand, Lawrence, which for twenty years used the polluted water of the Merrimack River without filtration, had during that period an invariably high typhoid mortality. Since the introduction of thorough filtration, at the advice of the State Board, its rank in the columns of this table has fallen to a position quite near the bottom of the list, and a mortality of only 1.86 per 10,000 in 1896.

Holyoke has a comparatively good public water supply, but for the first three five-year periods stood at the top of the list, with the highest typhoid mortality. It then fell to the sixth place in the fourth and the eleventh place in the fifth period, and then to the thirtieth in the year 1896. Upon investigation by the State Board of Health in 1891 it was found that, notwithstanding the good quality of its water supply, much water was taken for drinking purposes from the three canals, either directly or but imperfectly filtered by means of defective filtering galleries in the bottom of the canals. The authorities were advised to discontinue this practice.

It may be added as a general statement, in regard to these tables, that the mean typhoid death-rate of the cities in the first or upper half of the list in 1896 is less than the mean typhoid death-rate of the cities in the lower half in the period 1871–75, and that some cities which have maintained a comparatively uniform rate through the whole time from 1871 to 1896 have apparently risen in this table to a higher relative position, for the reason that this very marked improvement has taken place in many other cities.

In 1896, for the first time, there are three cities having a combined population of over 70,000 in which the typhoid death-rate was less than 1 per 10,000, and in one of them (Woburn) there were no deaths from this cause.

Consumption.

In the last annual report of the Board a copy of the circular issued by the Board in the preceding year was published. Soon after the publication of the circular, the attention of the Board was called to a monograph by Dr. J. B. Russell, the Senior Medical Officer of Health of Glasgow, which had recently been published in that city, entitled "The Prevention of Tuberculosis."

The practical tone of the book, and its clear and intelligent presentation of the subject, led the Board to reprint it for distribution in Massachusetts, with the consent of the author. An edition of five

thousand was published and distributed throughout the State. No publication of the Board has been received and read with greater interest, and it is hoped that much benefit will be derived from its free circulation. Copies may be had on application to the Board.

Diphtheria.

No disease or cause of death has received greater attention in recent years than diphtheria, and it is hoped that the vigorous action of health authorities now being conducted against this disease will be followed by similar results as appear to be taking place in the deathrate from tuberculosis. The efforts at prevention and restriction of disease now going on in all civilized countries may well receive the title usually given to them in German cities, "a campaign against infection."

In the interest of the health of the people the Board has therefore believed it proper to offer every possible facility to the different municipalities both for the diagnosis and for the preventive treatment of diphtheria.

For the first of these objects, the diagnosis of diphtheria, a system of examination of throat cultures has been established, whereby such cultures may be forwarded to the Board for examination from any city or town in the State, sets of tubes containing the culture material being deposited with boards of health and druggists in convenient locations. An account of the first year's work in this direction may be found in this report.

For the second object, the furnishing of antitoxine, the methods adopted by the Board have already been described in the report of last year, and a continuation of the subject is presented in this report.

Malarial Fever.

In 1885 malarial fever appeared for the first time as a serious epidemic in eastern Massachusetts at South Framingham, and was made the subject of a report by Dr. Z. B. Adams in the seventh annual report of the Board of Health, Lunacy and Charity, Supplement on Public Health.

From that time it appeared successively in other towns in the eastern part of the State, and reports have been made upon its operations by different writers.

The reports which have been published by the State Board of Health are as follows:—

Report of 1880, by Dr. J. F. A. Adams of Pittsfield. Report of 1885, by Dr. Z. B. Adams of Framingham. Report of 1889, by Dr. C. H. Cook of Natick. Brief statement in report of 1888 of its prevalence in Deerfield.

In addition to these, special examinations have been made of the territory along the banks of the Charles River from Dedham to tidewater. This examination was made by the Board, acting conjointly with the Metropolitan Park Commission, first of the region from Waltham to the sea, and secondly, of the region immediately above Waltham.

Investigations have also been made at Uxbridge, North Saugus and at Woburn, in each of which places there have been serious outbreaks of malarial fever. In a small district in Woburn, mostly upon the shores and territory contiguous to Horn Pond, a house-to-house inquiry revealed the fact that over 1,900 cases of malarial disease had existed in this district during the years 1894, 1895 and 1896 in a somewhat densely settled district covering an area of about one-half square mile.

OFFENSIVE TRADES.

No complaints were made directly to the Board during the year with regard to offensive trades, and consequently no hearings upon the subject were held. In consequence of the more efficient organization of local boards of health in the cities and large towns such matters have in the past two years been settled by the local boards.

In one instance the advice of the Board was asked as to the mode of dealing with a nuisance of this character located in the town of Mansfield, where an establishment existed for the purpose of conducting the business of making fertilizers in a very crude manner, the carcasses of animals being treated with acids out-of-doors and then covered with a light coating of soil, the effect being to produce a very foul odor in the neighborhood.

MANUAL OF HEALTH LAWS.

The Board has published at intervals of about four years, since 1882, an edition of the health laws of the State, each edition containing the health statutes in force up to the time of its publication.

An edition was published in 1894 which soon became exhausted, although a larger edition was printed than usual.

In 1896 a new edition was prepared, and was revised with unusual care by E. M. Parker, Esq., of Cambridge, the health laws in force up to January, 1897, being included. A new feature of the manual is the complete index of all the laws in force which precedes the text, each law being referred to by chapter and page of the manual. A very complete index is added at the end of the book.

As an aid to local health boards, physicians and court officers it will be found indispensable. The following partial list of its contents conveys an idea of its comprehensive character: general powers and duties of the State Board of Health, local boards, nuisauces, infectious diseases, vaccination, protection of infants, quarantine, offensive trades, water supply and sewerage, public baths, cemeteries and burials, cremation, cattle diseases, medical societies, color blindness, instruction in physiology, etc., sanitary work of district police, plumbing, stables, bakeries, food and drug inspection, registration of vital statistics, inquests.

LEAD POISONING.

This subject was mentioned in the last report of the Board, with special reference to the occurrence of an unusual number of cases of illness in the town of Kingston, which upon investigation by the Board was shown conclusively to have been caused by the presence of lead in the water of the public water supply, and which could only be accounted for by the free use of lead for service pipes in the town. The Board at that time, Sept. 23, 1895, wrote to the water board of Kingston, recommending the "immediate removal of all lead pipes in the town, wherever they are used for conveying water for domestic use, either as service pipes or as street mains."

Since that time other cases of similar character have been reported from other parts of the State, notably from Fairhaven, New Bedford and Milford, and further investigations are being conducted with reference to the action of the public water supplies upon lead pipe. The results of these investigations will be made known in a future report.

Inspection of Summer Resorts.

There has been for many years a limited number of places, at different points in the State, at which large numbers of people congregate during the summer months for longer or shorter periods of time. These were in some instances owned and controlled by relig-

ious or other organizations. They were usually located either on the seashore or upon the banks of a river or lake or pond. At some places cottages were built and quite a summer village was maintained, as in the case of Cottage City, Onset Bay, Brant Rock, Salisbury Beach, Pleasant Lake in Franklin County, etc. In other cases the camp or picnic ground was of a more temporary character, where people gathered in large numbers for a single day. The latter class of resorts has very greatly multiplied within the past ten years, their rapid increase being due largely to the development of electric railways in the neighborhood of the populous towns, and the desire of such corporations to provide amusement for their patrons.

In one instance, eight such resorts of different size and character have been established upon the shores of a single lake or pond, three upon another lake, and so on, and in some instances such places have been located upon the watersheds of public water supplies. In the case already noted, where eight places of this character exist upon one lake or pond, the water of the pond is the water of the public supply of the neighboring town. It is, however, filtered through the gravel and drawn from wells or galleries upon the shore of the lake.

It was, therefore, decided by the Board that an investigation of the sanitary condition of these places should be made, with several points in view, and with the intention of advising or recommending such changes as were deemed necessary to remedy defects and to improve existing unsanitary conditions. The special points which were kept in mind in the investigation were: First, the possibility of such places proving dangerous to public water supplies, in consequence of their location upon the watersheds. Second, as to the water supplies furnished to the patrons of these resorts. Third, the drainage and sewerage of the buildings. Fourth, their general sanitary condition, and especially that of the restaurants, kitchens, water-closets and the disposal of the garbage and other waste matters.

The investigation was under the management of Prof. W. T. Sedgwick and a corps of inspectors, and many places were also visited by the secretary.

The whole number of such places which existed in the State so far as was known at the time of the inspection was 130, and nearly all of these were visited personally and during the season of patronage.

Reports were made to the Board upon their sanitary condition, and letters were then issued to the proprietors of those resorts where existing conditions were unsatisfactory, describing the nature of the conditions which needed improvement, and in such instances as were necessary the aid of the Board was offered in examining and approving such plans as might be devised for the remedy of unsanitary conditions. In most instances the proprietors cheerfully complied with such suggestions as were made.

The distribution of these resorts by counties was as follows: -

| In Barnstable County, | | , | 1 | In Hampshire County, | | 3 |
|-----------------------|--|---|----|----------------------|--|----|
| In Berkshire County, | | | 4 | In Middlesex County, | | 19 |
| In Bristol County, . | | | 11 | In Nantucket County, | | 1 |
| In Dukes County, . | | | 6 | In Norfolk County, | | 12 |
| In Essex County, . | | | 11 | In Plymouth County, | | 5 |
| In Franklin County, | | | 4 | In Suffolk County, . | | 1 |
| In Hampden County, | | | 11 | In Worcester County. | | 41 |

WATER SUPPLY AND SEWERAGE.

When the State Board of Health was reorganized in 1886, upon a similar plan to that of the original board of 1869, a new law was enacted which gave to the Board enlarged powers and new duties of the highest importance, having special reference to the water supplies and systems of sewerage which constitute so large a share of the public sanitary works throughout the State. This law, entitled the "act to protect the purity of inland waters," often alluded to in these reports, has proved one of the most useful and comprehensive enactments of recent years. Under its provisions an engineering department was established, which has carried out all the important work of this character which has been accomplished by the Board during the succeeding years.

Among the transactions of this department of work, already noticed in the reports of the Board, may be enumerated the establishment of the experiment station at Lawrence, with the many important additions to science which have been made there; the maintenance of a laboratory in Boston for constant use in the examination of the waters of the State, with equally important discoveries and demonstrations of new principles in this department of work (e. g., the chlorine determinations of the waters of different localities at variable distances from the sea and their practical usefulness); the constant general supervision of water supplies and systems of

sewerage; the continuous examinations of these waters by means of chemical and bacterial analyses, as well as personal inspection of the sources of supply, especially of those of doubtful quality; the work of giving advice to cities, towns, corporations and individuals as to the selection of new sources of supply, the improvement and enlargement of old ones, the introduction of systems of sewerage and sewage disposal.

In addition to all these duties, the establishment of this department has made it possible for the Board to carry out the wishes of the Legislature in regard to the following matters, some of which may be reckoned among the most important public undertakings in the State: the devising of the metropolitan sewerage system, now being completed, started in 1889; the investigation of the sources of ice supply of the State (1890) and of manufactured ice (1893); the metropolitan water supply (1895), now in process of construction; the improvement of the Charles River, two reports (1894 and 1896); the improvement of the Concord and Sudbury rivers (the work of making these improvements was intrusted to the Board); improvement of the Neponset River; the sewerage of Salem and Peabody; and the investigation of the Green Harbor dike and marshes.

In the present report the details of the work performed by this department in carrying out its routine duties will be found under the head of "Advice to Towns;" "Examination of Water Supplies and Rivers;" "Summary of Water Supply Statistics;" "Work at the Lawrence Experiment Station in 1896;" and "Sewage Purification of Cities and Towns in Massachusetts."

Bacteriological Department for Investigations relative to the Prevalence of Infectious Diseases.

This department of the work of the Board was established at the Bussey Institute, near the Forest Hills station of the New York, New Haven & Hartford Railroad, in 1894, and at once became a most important adjunct to the work of the Board. Dr. Theobald Smith, Fabyan Professor of Comparative Pathology at Harvard University, has charge of the work of the laboratory, which now consists mainly of the diagnostic examination of suspected diphtheria cultures, of material forwarded to the Board to be examined for the presence of tubercle bacilli, of specimens from the blood of persons suffering with malarial symptoms, the preparation of diphtheria

antitoxin, and such investigations of an experimental character as are from time to time deemed necessary. In addition to the supply of diphtheria serum, a supply of tetanus antitoxin is also now prepared for such use as may be demanded.

Very much of this work is conducted under the difficulties incident to constant transmission of material by express and messenger service, and of daily correspondence with local boards and physicians by means of the mails, telegraphs and telephones.

Cities and towns in all parts of the State, including several in Berkshire County, at a distance of one hundred and fifty miles from the laboratory, have availed themselves of the advantages of this department.

This useful work has grown rapidly, and at the present time several of the local boards of health of large cities have organized departments of their own for the purpose of bacteriological examination. In one instance (in the city of Boston) the local board also maintains a plant for the production of antitoxin.

Some of the important operations of this department of the Board's work may be found detailed in this volume under the head of reports upon "Toxin Production," "Antitoxin" and "Malaria."

VITAL STATISTICS OF THE STATE.

It has been customary in recent years to publish in the annual report of the Board a condensed statement of the vital statistics of the State, since all correct deductions relating to the sanitary progress of a community must depend for their accuracy upon the records to be found in the returns of the vital statistics of cities and towns. In the present report special attention has been given to this subject by the presentation of a summary embracing the statistics of forty years, and including the period from 1856 to 1895, inclusive.

IMPROVEMENT OF THE CHARLES RIVER.

By the provisions of chapter 475 of the Acts of 1893 the Board together with the Metropolitan Park Commissioners were made a joint board to investigate the "sanitary condition and prepare plans for the improvement of the beds, shores and waters of the Charles River, between Charles River bridge and the Waltham line on Charles River, and for the removal of any nuisances therefrom."

The report of this joint board was made to the Legislature in April, 1894, and was also published in the twenty-sixth annual report of the Board (page exxxiii).

An act was passed in that year (1894) by which the joint board was continued and instructed to investigate the condition of the river from the point at which the previous investigation terminated as far as Mother Brook in Dedham, and to "report plans for its improvement and for the removal of nuisances therefrom."

This report was completed and submitted to the Legislature in May, 1896, and the general report of the joint board is published in this volume. The original report also contains a summary of the prevalence of intermittent fever in the region embraced in the report, by Dr. J. J. Thomas, who collected information relative to the occurrence of nearly five thousand cases of malarial disease in this region in the period 1890–94.

THE SEWERAGE OF SALEM AND PEABODY.

The city of Salem and the town of Peabody are two municipalities, the former lying upon Salem harbor and the latter adjoining Salem, but further inland. They have a combined population of nearly 45,000, and are without an adequate system of sewerage. The sewage of the city is discharged without system, along the shores, while that of Peabody, consisting largely of the drainage of tanneries, empties into the North River, which flows into Salem harbor at the northern boundary of the city and also receives sewage from Salem.

By the provisions of chapter 112 of the Resolves of 1895 the State Board of Health was "authorized and directed to consider and report a general system of drainage and sewerage" for Salem and Peabody, or "for such parts of said city and town, not all of which shall be wholly within either of said municipalities, as may, in the opinion of said Board, be best drained by said system."

By the terms of this resolve this report was to have been made in January, 1896, but the time was insufficient for the required survey, and was therefore extended by the provisions of chapter 69 of the Resolves of 1896 to January, 1897.

The general report of the Board upon this subject will be found in the present volume.

THE NEPONSET MEADOWS.

In the last annual report of the Board (1895) reference was made to the action of the General Court directing the State Board of Health to "investigate the sanitary condition of the meadows of the Neponset River, and the bed, shores and waters of said river in the towns of Canton, Sharon, Norwood, Dedham, Milton and Hyde Park, and report whether their condition is dangerous or injurious to the public health by reason of stagnant water, or refuse from manufactories, or other causes" (chapter 83, Resolves of 1895).

The investigations required by this resolve were completed and the report was made to the Legislature in May, 1897.

The general report is also published in this volume. The recommendations of the Board were as follows:—

- 1. Legislation to prevent the pollution of the river.
- 2. Removal of the flash boards at the dam at Mattapan, enlargement of cross-section of the river at certain points, and deepening and reconstruction of the channel wherever it is necessary to prevent flooding of the meadows.

GREEN HARBOR RIVER.

In the report of the Board for 1894 reference is made to a petition of those inhabitants of Marshfield living at Green Harbor, a settlement upon the seashore in the easterly part of that town. By the provisions of chapter 303 of the Acts of 1871 a dike was built across the outlet of this river about a half mile above its mouth, by which some two or three miles of salt marsh were converted into a fresh-water region.

Application was made to the Legislature for the removal of the dike. The question was referred to the State Board of Health and the Harbor and Land Commissioners in 1896, acting as a joint board, to investigate and report upon the matter. This investigation is now in progress.

LOCAL BOARDS OF HEALTH.

As towns increase in population, and consequently in the density with which the principal villages are settled, the need of efficient sanitary supervision becomes more apparent every year. Boards of health are organized in towns where no separate board has previously existed. Legislation is also being enacted every year, giving additional powers to boards of health and increasing their duties.

Among the duties imposed upon local boards in more recent years are those which relate to cattle diseases, the inspection of plumbing, the licensing of stables, the inspection of bakeries, the reporting of cases of infectious diseases and of annual mortality returns to the State Board of Health.

A question of considerable importance which has arisen in two different towns during the past year is the relation of local boards of health to such public institutions as exist in the different cities and towns.

Several circumstances in recent years have tended to bring the State and local boards of health into closer mutual relations to each other. (1) The enactment of statutes requiring annual returns of deaths to the State Board by local boards, and the immediate reporting of all infectious diseases by local boards. (2) The work undertaken by the State Board to assist local boards in the diagnosis of infectious diseases, and in the supply of antitoxin for the treatment of diphtheria. (3) The general supervision of water supplies and systems of sewerage, which was required of the State Board in 1886.

Reference has already been made in previous reports of the Board to the organization of the Association of Boards of Health, at whose quarterly meetings the representatives of the State and local boards meet for the discussion of all questions which pertain to municipal as well as to general hygiene. This organization has proved very helpful to those local boards which have availed themselves of its privileges.

The efficiency of the sanitary supervision of cities and towns may be in some measure shown by the vital statistics of the State for the past thirty years. It is one of the first principles of general hygiene that the death-rate increases with the density of population, other things being equal.

Hygienic conditions, however, may be so greatly improved as to offset the harmful effects of increasing density. During the past thirty years the population of Massachusetts has doubled in number, and the density has increased in like proportion (that of 1865 was 152 inhabitants per square mile, and that of 1895, 300); yet the death-rate has remained about the same throughout these thirty years, when long periods of time are considered and not single years.

The death-rates of the population of the three successive decades since 1865 were as follows:—

| Periods. 1866-75, | | | | | | | eath-rate. | |
|-------------------|--|--|--|--|--|--|------------|--|
| | | | | | | | | |
| 1876-85, | | | | | | | 19.35 | |
| 1886_95 | | | | | | | 19 68 | |

These figures, when considered in connection with the doubling of the density, may be taken as an index of decidedly improved sanitary conditions.

HEALTH OF TOWNS.

A digest of the principal facts of importance published in the annual reports of local boards of health occupies the final pages of this report. The general character of these reports indicates a decided improvement in the work of local boards, especially in the direction of the management and control of infectious diseases.

The table containing the number of cases and deaths from certain infectious diseases with the ratio of fatality which was formerly published in connection with this digest has been transferred from this portion of the report to that part which is entitled "Statistical Summaries of Disease and Mortality."

ROUTINE WORK OF THE BOARD.

During the year ending Sept. 30, 1896, the Board held meetings at least once in each month. Meetings of such of the standing committees as were necessary for the transaction of business were also held from time to time, as well as joint sessions with such other boards or commissions as were prescribed by the Legislature.

The office of the Board has been open throughout the year, as prescribed by the Public Statutes, chapter 21, section 10,* for the transaction of its authorized business.

Advice has been very frequently given at the office and by mail to local boards and to individuals in regard to sanitary matters, and many visits have been made by the secretary, the engineers and other experts to cities and towns for the purpose of making investigations and giving advice.

The work of the office has become materially increased in consequence of being made a central station for the distribution of antitoxin to local boards of health, hospitals and physicians in private practice. To this has been added during the past year the work of examining the products of certain infectious diseases for the purpose of determining their character, notably diphtheria, tuberculosis and malarial fever.

The statistics of mortality compiled from the weekly postal card returns from the registering authorities of cities and towns have been published weekly during the year in the form of a bulletin, which also contains, once in each month, a report of the work done in the

^{*} Office hours, 9 A.M. to 5 P.M.; Saturdays, 9 A.M. to 2 P.M.

line of food and drug inspection, together with the prosecutions made under the food and drug acts, and other important information relative to the work of this department. In addition to these items there is also published in the same bulletin a weekly report of the number of cases of infectious diseases reported by the local boards to the State Board of Health.

The following table presents certain statistical data relative to the routine work of the Board:—

| | STATIS | TICA | L TA | BLE | FOR | THE | YEA | R EN | DING | SEP | т. 30 | 0, 189 | 96. | |

| 1892 | | | | | | 56 | | | | | | | |

RECOMMENDATIONS.

The following recommendation was made to the Legislature at the beginning of the session of 1897:—

The Board recommends the continuance of its investigations now being carried on as authorized by the provisions of chapter 375 of the Acts of 1888. For this purpose, and to make the necessary investigations in order to advise cities, towns, corporations and individuals in regard to the best methods of assuring the purity of intended or existing water supplies and the best method of disposing of sewage, and to carry out the other provisions of chapter 375 of the Acts of 1888, the Board estimates that the sum of \$30,000 will be required.

EXPENDITURES.

The work of the Board is conducted under the provisions of several statutes, and for its different departments of work three appropriations are annually made, one for the general work of the Board, one for the inspection of food and drugs, and a third for carrying out the provisions of chapter 375 of the Acts of 1888, relating to the protection of the purity of inland waters. In addition to the foregoing, special appropriations have been made from time to time, as occasion has demanded, for the purpose of enabling the Board to conduct special lines of investigations.

The appropriations for the different departments of work in 1896 were as follows:—

| For the gene | ral wo | rk of | the F | Board | ١, . | | | | | \$15,800 |
|--------------|--------|-------|---------|-------|------|-------|-------|--------|-------|----------|
| For food and | drug | inspe | ection, | | | | | | | 11,500 |
| For carrying | out th | e pro | visio | ns of | chap | ter 3 | 75, A | cts of | 1888, | 30,000 |
| Total, . | | | | | | | | | | \$57,300 |

The expenditures in 1896 under the foregoing appropriations were as follows: -

REPORT OF THE JOINT BOARD

UPON THE

IMPROVEMENT OF CHARLES RIVER.

[xxxiii]

REPORT OF THE JOINT BOARD UPON THE IMPROVEMENT OF CHARLES RIVER.

To the Honorable the Senate and House of Representatives of the Commonwealth in General Court assembled.

The undersigned, members of the joint board, consisting of the Board of Metropolitan Park Commissioners and the State Board of Health, to whom was referred, by chapter 529 of the Acts of 1894, the investigation of the sanitary condition of Charles River and the preparation of plans for the improvement of the river and its banks from the line between Waltham and Watertown to Mother Brook in Dedham, and for the removal of any nuisances therefrom, respectfully submit the following report.

The two boards named in the act met for organization July 26, 1894. H. P. Walcott was elected chairman of the joint board, and H. S. Carruth secretary. Mr. Carruth resigned his position Jan. 1, 1896, and John Woodbury was chosen to succeed him. Messrs. Olmsted, Olmsted & Eliot were asked to consider the subject of the improvement of the river, and submit a report thereon. Mr. Eliot had been a member of the Charles River Improvement Commission, appointed under authority of chapter 390 of the Acts of 1891, and had subsequently been employed as consulting landscape architect in preparing the plans for the improvement of Charles River which were recommended by the joint board appointed to consider the same, and a report upon which was presented to the Legislature in April, 1894.

The condition of the river has been personally ascertained by members of the board at various times, and they have carefully considered the reports made to them by the experts employed, and have reached the following conclusions.

The position of the Charles River in its relation to the metropolitan district has, necessarily, a very great influence upon the health and comfort of the people living in its vicinity. So long as the stream was comparatively unpolluted, its banks were occupied at eligible sites by dwellings of the better sort. The increase of pollution and the consequent nuisance occasioned by it have driven from the banks throughout the lower portion of the river those who could afford to establish new homes in more attractive places, and the houses once occupied by these people have been taken by a poorer population, or by manufactories that seek the stream for commercial advantages or to be at a distance from neighbors likely to complain of offensive processes incident to the business there carried on. In concluding their report, the joint board of 1894 made this statement: "Your board feels that no treatment of the Charles River can be entirely satisfactory which does not regard the condition of the river above and in Waltham. At the boundary of that city, by the terms of the act under which we are directed to make our investigation and report, our labors end."

It will be remembered that the plan submitted by the commission of 1894 called for the preservation of the public reservation along the banks of the river up to the line between the city of Waltham and the town of Watertown. At certain points this public reservation is bounded by existing streets; at certain other points new streets would have to be constructed, for the purpose of limiting the amount of land to be taken to the smallest area necessary to procure a satisfactory reservation. It is understood that the appropriation subsequently made by the Legislature of that year for the purpose of enabling the Metropolitan Park Commission to take such land was not sufficient to carry out the entire plan as recommended.

One of the disagreeable incidents of the failure to complete this plan is shown by the use of a portion of the low land near the river in Waltham for the erection of a manufacturing establishment, which is likely to be an injury to the appearance of the banks and the comfort of residents in the vicinity; and we take this occasion to again call attention to the necessity of securing the banks of the stream below the Waltham line and above the centre of Watertown from still further encroachment.

It must not be understood, from the language just used, that we wish to banish from the banks of the stream all manufacturing establishments. We recognize the necessity to many of them of the location which they now occupy; but it is also true that

there are located here some manufacturing establishments which almost of necessity involve a greater or less injury to the district in which they are placed, and it does not seem to us reasonable that the centre of one of the most attractive portions of the metropolitan area should be forever given up to uses for which many less attractive spots are equally available.

The first thing likely to impress a person looking at a map of the district above the dam of the Boston Manufacturing Company at Waltham is the large area occupied by the water surface of the river above that point. On any pleasant day of the warmer season of the year this surface is a resort for boats of every description, used for the purposes of innocent and healthful enjoyment, not only by the people of the neighboring towns but by visitors from the whole metropolitan district, and, if nothing else could be done, it would be the part of wisdom to take for public uses this area, at least. Almost the only circumstance which at present seriously impairs the attractiveness or the healthfulness of this water surface and the banks bordering it is the use made of the water by the manufacturing establishments which control the principal dam. Whenever the water is drawn several feet below the level of the top of the dam, as it occasionally is in the seasons of protracted drought, the muddy banks or shores are exposed. As the stream for a large part of its course is still the public sewer of the district, much putrescible animal and vegetable matter is deposited upon these exposed banks and soon enters into decomposition, becoming a source of discomfort and positive injury even to the health of those who visit the stream for purposes of recreation or who live upon its banks.

To take such control of the stream as would prevent material changes in the level above this dam would probably inflict at most only a slight damage upon this manufacturing industry. It is a damage, however, that can readily be estimated and easily paid for. The limit which we should recommend to be placed upon the water of the river at this point and at all points where dams exist is that the establishments should be restrained in their use of the water of the river to the actual capacity of the river. That is to say, a diurnal variation of the surface of the water of the river is unavoidable, and does not appear to us to be the source of danger; but the river should at no time be so far drawn upon during the hours of

use of the water that the volume of water thus used could not be replaced by the accumulation through the portion of the day when the water is not used.

If it were possible to actually take possession of a strip of land on both banks of the river above the more closely built up portions of the city of Waltham, we believe, having regard to a long future, that it would be a wise investment; and we advise that some portions of the banks of the river should now be taken, either because they are so attractive in themselves that the loss of their attractiveness would be a serious injury to the appearance of the district, or because they are so unattractive that they are necessarily of small value, and likely to be occupied by objectionable establishments and residences.

In few districts in the metropolitan area have the residents themselves shown a more unselfish interest in the development of their local public grounds than along the banks of this stream, and the river is used as a place of healthful recreation by crowds drawn from beyond the limits of the towns that border upon the stream.

With that inevitable growth of population that is sure to come, the importance of this territory lying in the heart of the metropolitan district must year by year grow, and the difficulties of obtaining a public ownership just as rapidly increase.

Aside from the æsthetic and recreative interest which the beautiful shores of this river possess, and paramount to it, is the question of their healthfulness; and in this relation no disease has in recent years attracted more attention, or deserved more, than intermittent fever, or the disease due to the so-called malarial influences. The real importance of this disease cannot be measured by the deaths which are recorded as due to it. The disabling effects of it cling to the unfortunate subject for years, destroy the capacity for work and diminish the enjoyment of life. Communities which have long suffered from the disease would consider no expenditure of money extravagant which would free them from it; and portions of this district have already suffered enough in recent years to realize how grievous the hardships inflicted by a perhaps unnecessary malady are.

Amid all the uncertainties that surround the origin of the disease, the experience of mankind is united upon this, that variations in the water level of a stream or pond create conditions favorable to the spread of malaria. Nowhere in the district about Boston are these conditions of a variable water level, at the season of the year when the malarial influences are most active, more marked than above the dam at Waltham. The large amount of organic matter necessarily present in the stream undoubtedly contributes something to the danger. So long as the banks are covered by water the processes of decomposition go on slowly, but on the exposed shores sun and air hasten on these processes of decay, with results which the people have always instinctively and justly feared.

These considerations emphasize the desirability, from the sanitary point of view, of maintaining the river's surface at a level as nearly uniform as possible, and in this matter the interests of public health and popular recreation concur.

In November, 1894, the State Board of Health issued a circular, which was addressed to physicians living in the cities and towns bordering upon the Charles River from Watertown to Dedham, for the purpose of obtaining information in answer to the following questions:—

- 1. When did intermittent fever first appear in your town, judging from your own observations?
- 2. Has it been more or less prevalent in your town during the past five years than previously?
- 3. Have any means been taken for its prevention, such as the drainage of wet lands, or other methods of improvement?

Fifty-seven physicians replied to these circulars, many of them very fully. The compilation of the replies was intrusted to Dr. J. J. Thomas, who also visited personally all of the infected districts. Replies were received from West Roxbury, Jamaica Plain, Brookline, Dedham, Dover, Needham, Waltham, Wellesley and Weston.

The occurrence of a few scattered cases in these towns from 1875 to 1885 "points to the presence of infected foci which, under favorable conditions, have become starting-points for its spread in the infected region."

The following summary gives the results of the replies to the second question, relative to its comparative prevalence in the five years (1890-94):—

Total Reported Cases, by Years.

| | YEARS. | | | | | | | | | | | | | | |
|-------|--------|--|---|---|--|--|--|--|--|--|---|--|---|-------|--|
| 1890, | , | | • | • | | | | | | | • | | | 442 | |

| 892, | | | | | | | | | | | | | . | 1,355 | |
| 893, | | | | | | | | | | | | | | 1,291 | |
| .894, | | | | | | | | | | | | | , | 1,236 | |
| То | tal, | | | | | | | | | | | | | 4,983 | |

Prevalence, by Towns (1890-94).

| | CITIES | AND | TOWN | īs. | * | | Cases reported. | Population (1890). | Ratio per 1,000 of Population. |
|------------|--------|-----|------|-----|---|---|-----------------|--------------------|--------------------------------|
| Brookline, | | ٠ | | | | | 45 | 12,103 | 3.96 |
| Dedham, . | | | | | | | 12 | 7,123 | 1.68 |
| Dover, . | | | | | | | _ | 727 | - |
| Needham, | | | | | | | 62 | 3,035 | 20.40 |
| Newton, . | | | | | | | 4,266 | 24,379 | 175.00 |
| Waltham, | | | | | | | 434 | 18,707 | 23.10 |
| Wellesley, | | | | | | | 58 | 3,600 | 16.10 |
| Weston, . | | | • | | | ٠ | 100 | 1,664 | 60.10 |

Nearly ninety per cent. of the reported cases occurred during the months of May, June, July, August, September and October.

In regard to the condition of the land near the river, Dr. Thomas says: "Both along the river itself and beside the various tributary streams is found much swampy and poorly drained ground. Not only is this true, but in many places the river itself spreads out over

a considerable area, forming extensive shallows surrounded by a wider or narrower strip of marsh. At seasons when the water is low, many of the shallows are exposed, or partly exposed, to the air and sun, while retaining abundance of moisture; in other words, forming most favorable culture grounds for the malarial parasite. This exposure of large areas of surface, when the level of the water is lowered but a few inches, is seen not only in the bed of the Charles River but along many of its tributaries and in many of the ponds which lie scattered through the whole region, and even more in the case of artificial reservoirs constructed for manufacturing purposes, or for supplying water to neighboring towns and cities."

Two methods occur to us by which the preservation of the attractive features of the stream may be secured; one by actual purchase of so much of the river banks as may be necessary for this purpose, the other by some arrangement with the riparian owners, by means of which the banks of the river, to an appropriate distance from the stream, shall be controlled in such manner as not to interfere with full private enjoyment of them, but at the same time to prevent, from the public point of view, a harmful use of them.

Some of the higher banks of the stream are now in the hands of individuals who have built expensive houses and laid out ornamental grounds; for the present, at least, the interests of these owners are the same as those of the public,—the preservation of the river with all its attractive features. To them, therefore, the proposition to establish a line along the banks of the stream within which no changes shall be made without the consent of some public authority acting in the interests of all would be a benefit rather than a hardship, for they would be protected against injurious changes upon neighboring estates. It would not be advisable, in our opinion, to allow the public any right to enter upon the territory thus reserved, for there should at the same time be secured at convenient and attractive points sufficient areas for all the reasonable uses to which this river is now put,—uses which would be indefinitely multiplied in case the natural beauties of this district are maintained.

Estimates which have been made by persons in whose knowledge of the territory in question we have full confidence show that sufficient land might be acquired by purchase, where actual public ownership seems essential, and control of certain other high-priced or developed lands secured, the possession of which by the public

is not requisite unless an inferior use of them is feared, for a sum of money not exceeding \$300,000. In this sum are included the probable expenses of building some simple contrivances for the easy transfer of boats over the successive dams upon the stream.

To obtain the various results, the necessity of which has been thus briefly stated, it is, in our opinion, imperative that the following steps should be taken: -

- 1. That the high-water surface of the Charles River, from the dam at Watertown up to the Dedham line, should be made a portion of the metropolitan park system; that measures should be taken for securing a water level as nearly permanent as possible throughout the warmer months of the year; that arrangements should be made for the convenient transfer of boats over the dams on the river.
- 2. That certain lands be taken upon the banks of the river for places of public resort and convenience, and that rights be taken in all the remaining frontage on the river for the purpose of preventing obnoxious uses of the same.
- 3. That the whole area so secured be placed under the control of some public authority having power to protect and improve it.

REPORT

OF THE

STATE BOARD OF HEALTH

UPON THE

SEWERAGE OF THE CITY OF SALEM AND THE TOWN OF PEABODY.

[xliii]

REPORT

OF THE

STATE BOARD OF HEALTH

UPON THE

SEWERAGE OF THE CITY OF SALEM AND THE TOWN OF PEABODY.

To the General Court of Massachusetts.

The State Board of Health has investigated and considered a general system of drainage and sewerage for the city of Salem and the town of Peabody, as authorized and directed by chapter 112 of the Resolves of 1895 and chapter 69 of the Resolves of 1896, and submits the following report.

The resolves under which the work has been done are as follows: -

[CHAPTER 112, RESOLVES OF 1895.]

Resolve relative to Sewage Disposal and Drainage in Salem and Peabody.

Resolved, That the state board of health is hereby authorized and directed to consider and report a general system of drainage and sewerage for the city of Salem and town of Peabody, or for such parts of said city and town, not all of which shall be wholly within either of said municipalities, as may, in the opinion of said board, be best drained by said system. It shall be the duty of said board: — First. To designate the portions of said city and town which shall be tributary to and embraced in the district and system to be so reported, and to define the same by their report, with plans and maps. Second. To define and show, by suitable plans and maps, such trunk line and main branches as it shall recommend to be constructed, with outlet. Third. To consider the various methods of disposal of sewage and the application of such methods to any portion of the territory herein mentioned; and to define the methods by which said city and town, or

parts of said city and town, may utilize said trunk line and main branches as an outlet of a system of sewerage and drainage for said city and town and said parts of said city and town respectively; and to show the same by plans and maps. Fourth. To employ such engineering and other assistance as may be necessary for carrying out the objects of this resolve, and to cause such surveys and levels to be made as will enable said board to determine with accuracy the location and grades of said trunk line and main branches, and also such surveys and levels in said city and town, and parts of said city and town, as will enable said board to determine with accuracy the methods by which said city and town, and parts of said city and town, may respectively utilize said trunk line and main branches, and to report such methods by plans showing the main lines by which each may so provide for itself a system of sewerage and drainage with its outlet into said trunk line or main branches. Fifth. To define the size and capacity of said trunk line and main branches, and the materials of which they should be constructed and manner of construction, and such other particulars as will enable said board to determine the probable expense thereof; and to ascertain and report the cost of the construction of said trunk line and main branches and outlet, and to report a recommendation as to the methods of apportioning said cost. All expenses incurred by said board under the provisions of this resolve shall be reported to the governor and council, and all such expenses when approved by them shall be paid out of the treasury of the Commonwealth; but the total expenditure shall not exceed three thousand dollars. The Commonwealth shall be reimbursed for such expenditure under this resolve as shall have been approved by the governor and council in the following manner: - The town of Peabody and the city of Salem shall each pay such proportion of the above expenditure as the said board shall deem to be equitable, and the amounts so to be paid by each shall be assessed and collected by the treasurer of the Commonwealth at the time required for the payment of the state tax of said town and said city respectively. Said board shall make all reports required by this resolve to the general court on or before the first Wednesday of January in the year eighteen hundred and ninety-six. [Approved May 29, 1895.

[Chapter 69, Resolves of 1896.]

RESOLVE EXTENDING THE TIME FOR THE REPORT OF THE STATE BOARD OF HEALTH RELATIVE TO SEWAGE DISPOSAL AND DRAINAGE IN SALEM AND PEABODY.

Resolved, That there be allowed and paid out of the treasury of the Commonwealth a sum not exceeding one thousand dollars, to be expended by the state board of health in continuing the investigations relating to a general system of drainage and sewerage for the city of Salem and the town of Peabody, provided by chapter one hundred and twelve of the resolves of

the year eighteen hundred and ninety-five, said amount being in addition to the three thousand dollars provided for in said resolve; the Commonwealth to be reimbursed for such additional expenditure herein provided for as shall be approved by the governor and council, in the same manner as provided in said resolve. The time allowed for the completion of the report of said state board of health relative to said general system of drainage and sewerage for the city of Salem and the town of Peabody is hereby extended, and said board is directed to submit said report in print, together with plans and estimates of cost, to the city of Salem and the town of Peabody on or before the first day of July in the present year, and to present a duplicate of said report to the general court on or before the first Wednesday of January in the year eighteen hundred and ninety-seven. [Approved April 17, 1896.

The nuisances caused by the discharge of sewage about Salem have been the cause of complaint for many years, and much money has been expended in various ways to improve the sanitary condition of the city. The shores about Salem are generally low, and large areas of flats are exposed at low tide. The flats in many places have become offensive on account of the discharge of sewage upon them, and new sewers have been built from time to time to remove the sewage to other points of discharge.

The worst nuisance existing at present is found in the North River. This stream is the natural drain of a territory containing numerous tanneries and similar establishments, sewage from which is discharged directly into the stream. The sewage from these works is of a particularly offensive character, and contains a much greater amount of putrescible organic matter than is contained in an equal quantity of ordinary domestic sewage. Several house sewers are also discharged into this stream, but the quantity of house sewage is probably very small compared with the quantity of manufacturing sewage.

Above North Street bridge the North River is confined generally in a narrow channel, while below the bridge there is a wide tidal estuary. The slackening of the current of the river when it enters this estuary causes a deposit of the heavier matters from the sewage, and it is understood that dredging has been resorted to from time to time in order to remove deposits from the bottom of the river in this vicinity.

Nuisances exist in several other places about Salem, particularly in the South River and in Palmer's Cove. An intercepting sewer

recently constructed removes a small portion of the sewage formerly discharging into the South River and some of the sewage formerly discharging directly into the harbor to a point of discharge near the Philadelphia & Reading coal wharf; but this place of discharge is not likely to prove satisfactory, on account of the large areas of flats in the vicinity of the outlet and the slow currents in the harbor. Should the present conditions continue, the nuisances will inevitably grow worse with the increase of population and the consequent increase in the quantity of domestic and manufacturing sewage that will be discharged into the streams and tidal waters about Salem.

The Board has not thought it necessary to describe in further detail the existing nuisances, since the conditions are well known to the inhabitants of Salem and Peabody, and several attempts have been made in the past to provide a satisfactory remedy. Permanent relief from existing nuisances can be obtained only by purifying the sewage before discharging it near the shores, or by conveying it in a crude state to some point of discharge at such a distance from inhabited shores that it will become well diluted before any portion of it can reach any shore.

From a consideration of the whole question, it is evident that the most appropriate and least expensive method of disposing of the domestic and manufacturing sewage of Salem and Peabody is by discharging it into the sea, rather than by attempting to purify it upon land or to clarify it by removing the suspended matters so far as possible by the use of chemicals.

In order to determine the most appropriate point of discharge in Salem harbor, a careful study of the tidal currents at several points has been made by means of floats. The results of these experiments show that the tidal currents in Salem harbor are slow and weak, as compared with those in Boston harbor, at the places where the north and south metropolitan sewer systems discharge; and no strong tidal current is found at any point near the shore into which the quantity of sewage that is likely to be produced by Salem and Peabody could be discharged without danger that some of the solid matters from the sewage might be deposited upon the shores in the vicinity of the outlet. The experiments show that the sewage could be safely discharged at Great Haste Island at all stages of the tide without danger that it would produce a nuisance upon any shore, and

this is the most appropriate place for the disposal of the sewage; but the cost of conveying the sewage to this point would be so great for the present population that it is desirable to select a point nearer the shore, even though the conditions are somewhat less favorable for the satisfactory disposal of the sewage. Float experiments indicate that if the sewage should be discharged at Great Aqua Vitæ Beacon, about half a mile east of Fort Pickering, there is danger that with easterly or northerly winds floating matters from the sewage might be carried to the shore of Salem harbor, or even to the Marblehead shore on the south; but the wind would be likely to have less influence upon a body of water covered with sewage than upon the floats, and probably little if any trouble would be experienced from discharging the sewage at this point for several years. In view of the circumstances, it is recommended that the works be built to discharge the sewage at Great Aqua Vitæ Beacon, and if this point of discharge becomes objectionable the outlet can then be extended to Great Haste.

Investigations were also made to determine the feasibility and probable cost of disposing of the sewage by discharging it at a favorable stage of the tide at some point close to the shore of Salem harbor, and providing a reservoir to hold the sewage between the tides. A location for a reservoir was found upon Winter Island, and the investigations indicated that it would be practicable to dispose of the sewage by discharging it off Fort Pickering Light upon the outgoing tide; but on account of the extra cost of the reservoir, this plan would be more expensive than the plan for discharging the sewage continuously at Great Aqua Vitæ Beacon, and it would be less satisfactory.

The proposed sewer begins at the junction of Walnut and Central streets, near Peabody Square, in the town of Peabody, and extends through the valley of the North River into Salem, crossing the main line of the eastern division of the Boston & Maine Railroad, near the northerly end of the tunnel, and along the shore of Collins Cove to a proposed pumping station on the north-easterly side of the Philadelphia & Reading coal wharf at the shore of Salem harbor. The elevation of the bottom of the sewer at the point of beginning is 12.47 fect above mean low tide, and its diameter is 3 feet 2 inches. The grade of the bottom at the pumping station is 0.67 of a foot above mean low tide, and its diameter 6 feet.

At the pumping station all of the sewage will be raised by pumps to a height varying with the height of the tide, and will be discharged at all stages of the tide at Great Aqua Vitæ Beacon.

The sewer at its lower end at the pumping station has a capacity sufficient to remove 38,000,000 gallons of sewage in twenty-four hours if running two-thirds full, or 48,000,000 gallons if running full. The capacity of the sewer has been based upon an estimated daily quantity of 80 gallons of ordinary sewage per inhabitant for a population of 102,000, which may be reached at the present rate of growth in 1935, and upon a liberal estimate of the amount of manufacturing sewage that may be produced in the district within that time, with allowances for irregularity in the discharge of sewage into the trunk sewer.

The main trunk sewer is designed to receive sewage only, and the entrance of large quantities of storm water should be prevented. To this end, the connections of existing sewers in Salem, which now receive both sewage and surface water, with the main trunk sewer, should be provided with automatic regulators, as is done in the case of connections between sewers which receive storm water and the intercepting sewers in the city of Boston and in the metropolitan sewerage district, in order to prevent the flooding of the main trunk sewer and other tributary systems by these sewers at times of storm. The mingled sewage and storm water from existing sewers may at such times be allowed to discharge at present outlets.

It will also be necessary to limit the quality of the sewage that may enter the main trunk sewer or any of its tributaries so as to exclude substances from manufacturing sewage that will not flow through the sewers or will have to be taken out of the sand-catcher, and all matters that may clog the pumps.

In some mechanical and manufacturing processes a considerable portion of the water used may not be fouled to an appreciable extent, and such water should not be discharged into the sewers, but should be disposed of by discharging it into the sea or into some suitable drainage channel.

The total cost of the main trunk sewer, with pumping station and other appurtenances complete, having an outlet at Great Aqua Vitæ Beacon, is estimated to be \$440,116.

On account of the topography of Salem and Peabody, and the fact

that only two municipalities are mentioned in the resolve, no main branches are found to be necessary, within the meaning of the resolve.

In Peabody no general system of sewers has as yet been constructed, and it is recommended that when the town shall provide itself with a system of sewers, the separate system be employed, and that surface water and, so far as possible, ground water be excluded from the sewers. In Salem some of the existing sewers will, by means of extensions, serve as main lines of sewerage for the city.

In extending the present sewerage system of Salem it is recommended that all new systems of sewers be constructed upon the separate plan and that storm water be wholly excluded. It is also very desirable that the area from which storm water is admitted to existing sewers should be restricted as much as is practicable, in order to avoid the expense of pumping considerable quantities of storm water and to limit as much as possible the discharge of crude sewage in the vicinity of the shores at times of storms.

The resolves under which this work has been done require that the Board shall ascertain and report the cost of construction of a trunk line sewer and main branches and outlet, and report a recommendation as to the method of apportioning said cost. In the case of the metropolitan sewerage system, which includes the city of Boston and twenty-one neighboring municipalities, the act providing for the construction and operation of the system contains a provision that there shall be a new apportionment of the charges for interest, sinking fund and maintenance once in five years; and a precedent for the apportionment of the cost of construction and of maintenance and operation of the metropolitan sewers among the several cities and towns composing the metropolitan sewerage district has already been well established by the reports of two commissions appointed by the supreme court to make such apportionment. The same method of apportionment has been adopted by both commissions, and is as follows: charges for interest and sinking fund, which represent the cost of construction of the works, are based upon the valuation of the municipalities included within the district, and the charges for maintenance and operation are based upon the population. In the cases of cities or towns portions of which cannot be drained by the metropolitan system, the valuation and population of such portions were excluded in favor of the city or town within whose limits these areas are situated.

There appears to be no more equitable method of apportioning the cost of construction of the Salem and Peabody system between these municipalities, and accordingly this method is recommended. The property valuations used by the commission appointed to apportion the cost of metropolitan sewers, which reported recently (the report being dated Oct. 16, 1896), are those established by chapter 90 of the Acts of 1895, and the valuations of Salem and Peabody established by that act are as follows:—

| Salem, | | | | • | • | | \$30,649,889 00 |
|----------|---|--|--|---|---|--|-----------------|
| Peabody, | 4 | | | • | | | 8,039,864 00 |

The proposed drainage district of Salem and Peabody includes the whole of Salem, but 6.6 square miles, or 4,224 acres, in the town of Peabody will not be drained by the proposed plan. It is therefore necessary, in deciding the proportion that Peabody should pay toward the cost of the works, to determine the valuation and population of the town, exclusive of the portion outside the proposed sewerage district.

The valuations furnished by the Tax Commissioner and established by chapter 90 of the Acts of 1895 give the total valuations of the cities and towns, and it is not possible to determine exactly the valuation of the territory in the town of Peabody which will not be reached by the proposed sewer. The most accurate approximation that could be made appeared to be the following: it was possible to obtain from the assessors of Peabody the total valuation of real and personal estate in the whole town and in the portion of the town outside the proposed sewerage district for May 1, 1895. was also possible to obtain from the Tax Commissioner the total amount of bank and corporation stock belonging to Peabody in 1894; and one of the Peabody assessors, after an examination of the records of the Tax Commissioner, made a statement as to the amount of this stock that was chargeable to the portion of the town outside the proposed sewerage district. The percentage of the total valuation of the town that is represented by the valuation of the portion outside the proposed sewerage district has been obtained from these amounts, as follows: -

| Assessors' valuation of all real and personal estate in Peabody (1895), | |
|---|----------------|
| Tax Commissioner's valuation of all corporation and bank stock belonging to Peabody (1894), . 786,375 00 | |
| Total for town of Peabody, | \$8,385,125 00 |
| Peabody outside of sewerage district, \$819,250 00 Tax Commissioner's valuation of corporation and bank stock belonging in Peabody, outside of | |
| sewerage district ascertained as above (1894), . 105,700 00 | |
| Total for area in Peabody outside of sewerage district, | 924,950 00 |
| Net valuation of sewerage district, | \$7,460,175 00 |
| age district, | 11.03084 |

Deducting this percentage from the total property valuation of Peabody made by chapter 90 of the Acts of 1895, which is \$8,039,-864, the total valuation of property in the proposed sewerage district is as follows:—

| Salem, . | | • 1 | | | | . \$30,649,889 00 |
|----------|--|-----|--|--|---|-------------------|
| Penbody, | | | | | • | 7,152,999 00 |
| Total, | | | | | | . \$37,802,888 00 |

The percentage of each to the total and the proportion which each municipality should pay toward the cost of the works under this apportionment at the present time is as follows:—

| Salem,. | | | 4 | | | 81.0782 per cent. |
|----------|--|--|---|---|--|-------------------|
| Peabody, | | | | • | | 18.9218 per cent. |

The estimated annual cost of maintenance, including all running expenses and repairs, of the trunk sewer, pumping station and harbor outfall for Salem and Peabody, discharging at Great Aqua Vitæ Beacon, is \$12,000. The present quantity of sewage produced by Salem and Peabody is estimated at 6,250,000 gallons per day, and the estimate for maintenance is based upon a quantity of sewage equivalent to 10,000,000 gallons per day, which may represent the average quantity of sewage to be disposed of for ten or more years in the future.

In estimating the proportion which each municipality should pay toward the maintenance and operation of the system, the basis used by the commissioners who apportioned the cost of metropolitan sewers, as already stated, is the population; and here, also, it is necessary to make allowance for the number of people in the portion of Peabody outside of the proposed sewerage district. It has not been thought necessary to attempt to determine this population with great accuracy, since an accurate estimate can be made when occasion may require. By a count of the houses in the district outside of the area draining toward the proposed sewer, it is found that there are about 103 houses in this district. Allowing a population of 5 persons to each house, the number of people in this district would be 515. Deducting this number from the population of Peabody, as determined by the census of 1895, the estimated number of people within the proposed sewerage district in the town of Peabody is 9,992.

Dividing the cost of maintenance and operation upon the basis of population, estimated as above, the proportion which Salem and Peabody would pay is shown by the following table:—

| | | | | | Population, 1895. | Per Cent. of Cost of Maintenance. |
|----------|--|--|--|--|-------------------|-----------------------------------|
| Salem, . | | | | | 34,473 | 77.53 |
| Peabody, | | | | | 9,992 | 22.47 |

In constructing public works of this magnitude it is customary to raise the money for the work by issuing bonds, and in cases like the one under consideration, where the works are expected to serve for many years in the future, bonds are issued for long terms. Payment for the bonds is provided for generally by payments to a sinking fund, the payments being so arranged as to extinguish the debt at the maturity of the bonds. In order to indicate approximately what the probable yearly cost to each municipality would be, should bonds be issued for the construction of the works and a sinking fund created to pay them at maturity, the following estimate has been prepared. The interest charges have been assumed to be 4 per cent., which appears to be the average rate of interest on town and city bonds issued under favorable conditions within the last few years, although such bonds would command a premium at the present time; and the sinking fund has been estimated at 14 per cent. annually, which would extinguish the debt in forty years.

| Estimated ye | early | cost | for | inter | est a | nd si | nking | g fun | d, at | 51 | |
|--------------|-------|------|------|-------|-------|-------|-------|-------|-------|----|-------------|
| per cent., i | is. | | | | | | | | | | \$23,106 09 |
| Estimated ye | early | cost | of m | ainte | nance | e is | | | | | 12,000 00 |
| Total, | | | | | | | | | | | \$35,106 09 |

Dividing these two amounts between Salem and Peabody, on the basis of apportionment already given, the total yearly cost and the cost per capita tax to each municipality would be as follows:—

| | | YEARLY COS INTERE AND SINKING | ST | YEARLY COS MAINTENA | | YEARLY COST FOR INTEREST, SINKING FUND AND MAINTENANCE. | | | |
|----------|---|-------------------------------------|----------------|------------------------|----------------|--|----------------|--|--|
| | | Total. | Per Capita. | Total. | Per Capita. | Total. | Per Capita. | | |
| Salem, . | | \$18,734 00 | \$0 54 | \$9,303 60 | \$0 27 | \$28,037 60 | \$0 81 | | |
| Peabody, | ٠ | 4,372 09 | 44 | 2,696 40 | 27 | 7,068 49 | 71 | | |

Should the State create a district, and should it construct and operate the main sewer system herein proposed in the same manner as in the case of the metropolitan sewerage district, and charge the amounts for interest, sinking fund and maintenance to the city of Salem and the town of Peabody, a considerable saving would be made in the cost of interest and sinking fund to Salem and Peabody.

In the case of the metropolitan sewerage loan, the bonds bear interest at a rate of 3 per cent., but at the present time the rate of interest upon State bonds would probably be higher. Assuming that the rate of interest would be $3\frac{1}{2}$ per cent. (at which rate the bonds would command a premium at present), and that the payment to the sinking fund would be $1\frac{1}{4}$ per cent., as before, the annual cost to Salem and Peabody would be:—

| Estimated a | nnual | cost | tof | inter | est ai | nd sin | nking | fun | d, at | 43 | |
|--------------|-------|------|------|-------|--------|--------|-------|-----|-------|----|-------------|
| per cent., i | is. | | | | | | | 4 | | | \$20,905 51 |
| Estimated an | nual | cost | of n | ainte | enanc | e is | | | | | 12,000 00 |
| Total. | | | | | | | | | | | \$32,905 51 |

This would be at a rate of \$2,200.58 per year less than if the towns raised the money themselves; or, in other words, the use of the credit of the State would reduce the yearly cost for interest and sinking fund by about 9½ per cent.

The total cost and cost per capita to each municipality would then be as follows:—

| | | YEARLY CO. INTERE AND SINKING | ST | YEARLY COS MAINTENA | | YEARLY COST FOR INTEREST, SINKING FUND AND MAINTENANCE. | | | |
|-------------------|--|-------------------------------------|----------------|------------------------|---------------|---|----------------|--|--|
| | | Total. | Per Capita. | Total. | Per Capita | Total. | Per Capita. | | |
| Salem, Peabody, . | | \$16,949 81 3,955 70 | \$0 49 40 | \$9,303 60 2,696 40 | \$0 27 27 | \$26,253 41 6,652 10 | \$0 76 67 | | |

By a provision of the resolves under which this investigation has been made, it is required that the town of Peabody and the city of Salem shall each pay such proportion of the expenditure as the Board shall deem to be equitable.

It is deemed equitable that the cost of the preliminary investigation should be provided for in a manner similar to that which would probably be used in providing for the payment of the cost of the works; that is, that the cost of the investigation should be divided upon the basis of the valuation of the portions of each municipality included within the proposed drainage district. The appropriations and total cost of the work have been as follows: -

| Appropriations, | | | | | | | | • | | | | \$4,000 | 00 | |
|---------------------|----------|-------|---------|-------|-----------|-----------|------|---|---|-----|----|---------|------|--|
| | | | | Evn | *** TO 10 | FIT D 120 | | | | | | | | |
| Expenditures, | | | | | | | | | | | | | | |
| Salaries of engine | | | | | | | | | | | | \$3,301 | 50 | |
| Travelling expens | es, | | | | | | | | | | | 88 | 14 | |
| Labor in making | borin | gs, | | | | | | | | | | 345 | 54 | |
| Pipe and material | for k | oorin | gs, | | | | | | | | | 29 | 49 | |
| Glass bottles for s | | | | | | | | | | | | 8 | 88 | |
| Teaming, | | | | | | | | | | | | 10 | 00 | |
| Lumber, | | | | | | | | | | | | 7 | 75 | |
| Hardware, . | | | | | | | | | | | | 5 | 41 | |
| Tin cans for floats | | | | | | | | | | | | 4 | 25 | |
| Drafting, | | | | | | | | | | | | 80 | 00 | |
| Rental of instrum | | | | | | | | | | | | 15 | 00 | |
| Drawing material | | | | | | | | | | | | | 11 | |
| Maps and map me | | | | | | | | | | | | 17 | 85 | |
| Stationery, postag | | | | | | | | | | · | | 2 | 50 | |
| Expressage, . | | | | | | | | | | · · | | _ | 11 | |
| Telephone and tel | | | | | | | | | | · | i. | | 53 | |
| Miscellaneous inc | ident | als | Cooking | 500, | • | | | | | | • | | 45 | |
| zazoccizanoous inc | i ctom b | , | • | • | • | | • | • | • | • | • | | - TO | |
| Total owners | . J. C. | | | | | | | | | | | 40.040 | F-1 | |
| Total expend | ed 10 | r sur | veys | and n | oves | uganc | ons, | | | | • | \$3,943 | 51 | |

Dividing this amount on the basis of valuation of each municipality, the amount to be paid by each as its share of the cost of surveys and investigations is as follows: -

| | | | | | | | | | Percentage to | |
|----------|---|---|---|---|---|---|---|---|---------------|------------|
| Salem, . | | | | | | | | | be paid. | Total. |
| Peabody, | • | • | • | | • | • | | • | 81.0782 | \$3,197 33 |
| | • | • | • | • | ٠ | | • | | . 18.9218 | 746 18 |

To these amounts there is to be added, under a ruling of the State Auditor, the cost of printing reports for each municipality, with maps and plans, making the total assessment of each municipality as follows : --

| SALEM. | | |
|---|----------------------|------------|
| For proportion of cost of surveys and investigations, For printing of 730 copies of report (including plans), Total assessment, | \$3,197 33 223 29 | \$3,420 62 |
| PEABODY. | | |
| For proportion of cost of surveys and investigations, | \$7 46 18 | |
| For printing of 475 copies of report (including plans), | 145 29 | |
| Total assessment, | | \$891 47 |

and the Board deems it equitable that the city of Salem shall pay \$3,420.62 and the town of Peabody \$891.47 as their proportion of the above expenditures.

The reports of Mr. G. A. Kimball, the engineer employed by the Board to conduct the investigations and prepare plans of the works, and of Mr. Joseph P. Davis, the consulting engineer of the Board, appear in the special report presented to the Legislature.

REPORT

OF THE

STATE BOARD OF HEALTH

UPON THE

SANITARY CONDITION AND IMPROVEMENT OF THE NEPONSET MEADOWS.

REPORT

OF THE

STATE BOARD OF HEALTH

UPON THE

SANITARY CONDITION AND IMPROVEMENT OF THE NEPONSET MEADOWS.

To the Honorable the Senate and House of Representatives of the Commonwealth in General Court assembled.

The State Board of Health, acting under chapter 83 of the Resolves of 1895, has investigated the sanitary condition of the meadows on the Neponset River in the towns of Canton, Sharon, Norwood, Dedham, Milton and Hyde Park, and herewith submits the results of that examination, together with recommendations for the improvement of the sanitary condition of these meadows and the removal of nuisance therefrom.

These meadows cover an area of 3,662 acres. Of this surface hardly more than 600 acres appear to be in a condition adapted to profitable agriculture. From the remaining territory crops of hay are obtained occasionally, or not at all. The condition of the meadows seems to have grown worse in recent years, and many of the larger owners have abandoned the attempt to secure some degree of drainage by the maintenance of open ditches, on account of the steadily diminishing returns from the crops.

At an earlier day and for a succession of years a grass known as the fowl meadow or false redtop grew on these meadows, — the first name still is used to designate the locality, — and, proving to be a valuable forage plant, gave a high value to the lands upon which it flourished. The present condition of the territory, however, is evidently not so favorable as it once was to the growth or preservation of this grass, and it is also probable that cheaper transportation

has brought into this market hay of a better quality at a price lower than that at which this marsh grass could be profitably sold. As a result of either or both of these conditions, the value of these lands has steadily fallen.

While it might be expected that the meadows should be uninhabited, as they are, it is not at first so easy to understand why the higher grounds in the vicinity should be still unoccupied by the rapidly increasing suburban population which seeks and finds acceptable building sites at distances from the business centre of Boston more considerable than any portion of the area in question. The facilities for transportation by convenient railroads are at least as good as can be found in other directions from Boston, and the towns which make up the district appear to be desirable places of residence. There has, however, for years existed a popular belief that the meadows have become a source of sickness, and this feeling seems recently to have increased. Intelligent observers report that these meadows are at times the source of disagreeable odors and the direct cause of much sickness. The examinations by this Board have shown that the upper portion of the stream was very seriously polluted, and the opinions of the physicians residing and practising in the valley, which have been from time to time collected, indicate a general belief on the part of the medical profession that the conditions affecting health here are more unfavorable than they formerly

The valley of the Neponset River has twice before been the subject of extended examinations by the State authorities, — first by the State Board of Health in 1875, and subsequently by the Massachusetts Drainage Commission in 1885. In addition to these examinations, a description of the Neponset River basin, with statistics relating to its pollution and analyses of its waters, may be found in the special report of the State Board of Health on the examination of water supplies, 1890, and in the twenty-second annual report of the Board. So much of the great body of facts collected by the Board as may be necessary for the purposes of this report will be found in the report of the engineer, contained in the special report presented to the Legislature.

The earliest notices of these meadows give evidence that even then there were prolonged periods of flooding, and that it was found necessary to clear the bed of the stream from time to time of its obstructions, consisting of fallen trees and shrubs with the entangled rubbish. With the increasing pollution of the stream, however,

another and more persistent interference with the current became operative. The waste matters of human life and the refuse of manufactories, when added to the waters of the stream, became efficient fertilizers for the vegetable substances that find a home there, and their increased quantity became a mechanical hindrance to the current, promoted deposits in the bed of the stream, and finally, by their decay, gave to the atmosphere odors which common experience as well as scientific knowledge declare to be injurious to health.

An accurate estimate of the amount of sickness produced by the condition of these meadows, founded upon statistical inquiry, is almost impossible, and largely for the reason that the common-sense of the people and their freedom to select more salubrious locations have prevented settlements in the immediate vicinity of these low lands. We find here, at an average distance of thirteen miles from the State House, an area of more than eleven square miles which is uninhabited. The people have not had the same objections to residence near the great salt marshes which line our coast, where the conditions of flooding and soil moisture are apparently as serious as they can be in the Neponset valley, but are not associated with a seriously polluted water or excessive growth and decay of vegetable matters.

We are of the opinion that the condition of these meadows and of the beds, shores and waters of the Neponset River is injurious to the public health. The opinions of the physicians of this district, as ascertained by an inquiry instituted by the Board, are also distinctly to the effect that the conditions which now exist here are unfavorable to health and that the unhealthful conditions are increasing in amount from year to year.

One disease has attracted considerable attention in recent years in many portions of this State, — malarial fever, — and portions of this valley have suffered from it, and severely, when the limited population is taken into account.

One farm-house was found not far removed from the meadows, but lying many feet above their level, which, well built and well cared for, had failed to offer adequate protection against an influence which, originating beyond the immediate surroundings of the house itself, was sufficiently potent to affect more than half of the ten occupants of the house.

We find that malarial diseases are uniformly prevalent in the Neponset basin, though no distinct concentration of cases has been anywhere observed except in the case of the farm-house above cited. This is a condition of things which points distinctly to some influence which pervades the whole district, and the obvious origin of such an influence is the condition of the Fowl Meadows, with the polluted river and large areas of stagnant water. While the current theories upon the subject of malarial diseases may sufficiently explain the occurrence of these diseases in a marshy region, with stagnating water and the inevitable accompaniment of decaying vegetation, we are well aware that future scientific examination may find the really essential factor in some hitherto unsuspected condition of such territories. But it fortunately is true that malarial diseases where once prevalent have disappeared upon the removal of conditions such as those now found through the Neponset valley, and that the general healthfulness has been distinctly and immediately increased thereby.

Attention is also called to the report contained in appendix prepared by the chemist of the Board.* With the co-operation of the owners of the larger manufactories on the river, a very complete examination has been made of methods for diminishing the pollution of the stream by treatment of the effluents from these establishments, and it has been found that these effluents, either by themselves or when mixed with ordinary town sewage, can be satisfactorily purified upon properly prepared sand filters. It is advisable, however, to remove by sedimentation from the factory effluent, before it reaches the filter, so much of the sludge contained therein as is possible. This sludge can be removed from the sewage by means of a settling basin of moderate dimensions, and, as it contains much more nitrogen than ordinary sewage, could probably be readily disposed of.

For the present, at least, the sparsely settled districts adjoining the meadows do not appear to be in pressing need of extended systems of sewerage; but the time will come when the same provision which is here recommended for the factory refuse should be made for the collection and purification of domestic sewage. There appear to be in the valley areas of land suited to intermittent filtration, and sufficient in quantity for the needs of the district.

Portions of the banks of the stream in the town of Hyde Park are at present in an unsanitary condition; but legislation subsequent to that authorizing this inquiry by the Board has provided a sufficient means for the relief of this state of things, through the construction of a sewer system having an outlet into the metropolitan system of sewerage.

^{*} This may be found in the special report of the Board upon the Neponset meadows, presented to the Legislature of 1897.

The measures which we recommend for the remedy of the conditions injurious to health now existing in the Neponset valley are these:—

First. — Such additional legislation as will prevent the entrance into this stream of sewage and manufacturing wastes which have not been satisfactorily purified.

Second. — The permanent removal of the flashboards of the dam of the Mattapan Mills, the enlargement of the cross-section of the river, together with a deepening and reconstruction of the channel at such places as may be found necessary for making a channel of such width and grade as will prevent the flooding of the meadows during the times of high flows in late spring and summer.

A conservative estimate of the cost of making this improvement, irrespective of land and water damages, is, in round numbers, \$125,000. The engineer also presents some figures*to show the increase in the value of meadow lands reclaimed, and to this sum should also be added the enhanced value of the now neglected building sites immediately adjoining the meadows. It can thus be demonstrated, we think, that the work of improvement would be justifiable from a money stand-point alone. We have not considered it within our province to present the agricultural advantages of a drainage of this expanse of meadows. Land so well adapted, as this would be when drained, to the purposes of market gardening must always have a value near a great market far in advance of any price now paid for land in this district.

When we limit ourselves, however, to considerations of health, it scarcely seems necessary, now that a considerable portion of the State has acquired a knowledge of the depressing and disabling effects of malarial diseases, to insist upon the economical value of a freedom from the conditions that favor their prevalence. We do not hesitate, therefore, to recommend the improvement of this district, the healthfulness of which is vital to the immediate residents therein, as well as to the occupants, present and future, of the lands lying about it.

It will be remembered that, in accordance with the recommendations of the Massachusetts Drainage Commission, legislation was had now embodied in chapter 375 of the Acts of 1888. Under the provisions of this act the State Board of Health has the general oversight and care of all inland waters. The commission which suggested

^{*} To be found in the report of the engineer, which accompanies the special document on the Neponset meadows, presented to the Legislature of 1897.

the legislation above referred to used these words in their report to the Legislature of 1886:—

Let these guardians of inland waters be charged to acquaint themselves with the actual condition of all waters within the State as respects their pollution or purity, and to inform themselves particularly as to the relation which that condition bears to the health and well-being of any part of the people of the Commonwealth. Let them do away, as far as possible, with all remediable pollution, and use every means in their power to prevent further vitiation. They shall put themselves at the disposal of manufacturers and others using rivers, streams or ponds, or in any way misusing them, to suggest the best means of minimizing the amount of dirt in their effluent, and to experiment upon methods of reducing or avoiding pollution. They shall warn the persistent violater of all reasonable regulation in the management of water of the consequences of his acts. In a word, it shall be their especial function to guard the public interest and the public health in its relation with water, whether pure or defiled, with the ultimate hope, which must never be abandoned, that sooner or later ways may be found to redeem and preserve all the waters of the State.

The suggestions contained in these sentences have governed the action of this Board during the ten years which have passed since the State Board of Health was made the official guardian of the inland waters of the Commonwealth. It is our opinion that all reasonable efforts have been exhausted in the attempt to do away with the remediable pollution of these waters, and that the time has come when the State must take more effective measures for the prevention of the pollution of the streams not now used as sources of domestic water supply, but still capable of injurious effect upon the public health.

WATER SUPPLY AND SEWERAGE.

ADVICE TO CITIES AND TOWNS.

WATER SUPPLY AND SEWERAGE.*

[Report required by the provisions of chapter 375 of the Acts of 1888, entitled "An Act to protect the purity of inland waters, and to require consultation with the State Board of Health regarding the establishment of systems of water supply, drainage and sewerage."]

The following report contains a summary of the work of the State Board of Health during the year 1896, under the provisions of chapter 375 of the Acts of 1888, including the substance of the replies made by the Board to those cities, towns, corporations and individuals which have applied to the Board for its advice relative to systems of water supply, drainage and sewerage, under the requirements of this act, and of special acts which include a clause requiring the approval by the Board of plans and schemes relative to water supply and sewerage, together with a brief statement of the work done at the experiment station at Lawrence and in connection with the examinations of water supplies and rivers.

During the year 1896 public water supplies were introduced in the towns of Hatfield, Rutland, Weston and Winchendon, and important additions to the sources of many existing works were made. At the end of the year 1896 all of the 31 cities in the Commonwealth and 127 towns out of a total of 322 were provided with public water supplies. The total population of the communities having a public water supply is 89.8 per cent. of the total population of the State. There are now but 3 towns which by the census of 1895 have a population exceeding 3,500 which are not provided with a public water supply. The names of these towns, with their respective populations in 1895, are as follows:—

| Towns. | | | | Population. |
|----------------|--|---|--|-------------|
| Blackstone, . | | ٠ | | 6,039 |
| Barnstable, . | | | | 4,055 |
| North Andover, | | | | 3,569 |

^{*} The first pages of this report were contained in a report made to the Legislature Jan. 11, 1897 (Senate Document, No. 4). A portion of the report then made, relating to the work done at the Lawrence Experiment Station, is not reproduced, because a more complete account of the work done at this place will be found in a subsequent part of this volume.

The flow of streams for the year 1896, as indicated by the Sudbury River, was slightly less than the normal for twenty-two years. The flow was greatly in excess of the normal in February, March and September, and slightly in excess in October. It was less than the normal in all of the remaining months, the most marked deficiency being in the months of April, May, July and August.

The chemical analyses of the water supplies and rivers of the State and of sewage and effluent from sewage disposal works have been continued during the year, 2,399 samples having been examined. The following is a classified list of the waters examined during the year:—

The examination of the microscopic organisms has been continued in the waters which have been examined chemically, as in previous years.

The laboratory for water analysis, which has heretofore been located at the Institute of Technology, was removed at the end of 1896 to rooms set apart for it in the new portion of the State House.

Systems of sewage disposal have been introduced during the year in the towns of Natick and Leicester and at the Westborough Insane Hospital. At the present time there are 11 cities and towns, having an aggregate population of 98,287, in which the purification of the sewage is effected by filtration through beds of gravel or sand, and the sewage of several large public institutions also is disposed of by this method.

References have frequently been made in these reports to the presence of iron in ground waters, and its effect upon the quality of water supplies in which it occurs in excessive quantity. In some cases the quality of the water has been so objectionable as to cause extensive changes in the source of supply, and even an abandonment of the source for this cause, and the problem of improvement of such waters has been the subject of careful investigation by the Board during the past year, and important results have been obtained.

The condition in which the iron exists in water varies in different sources and even in the same source at different times. In one of the towns of the State (Provincetown) it was not feasible to obtain a source of water supply free from iron, and iron has been present in this water in objectionable quantity from the time the supply was first introduced. In this supply iron is found combined with organic matter in such a way that the water is not only objectionable on account of the excess of iron present but on account of the high color of the water.

Water was first introduced into the town in 1893, and, while the quantity of iron at that time was large, it has increased rapidly from year to year, so that at the present time the water contains nearly four times as much as during the first year of its use. Investigations with reference to the purification of this water were begun in the early part of 1896, and have been continued through the year. Experiments upon the filtration of the water through various materials have shown that, by filtration through a filter composed of fine coke, known commercially as coke breeze, practically all of the iron can be removed, and a clear and colorless water obtained which has not been injuriously affected in other respects by the process of filtration. In consequence of the favorable indications furnished by these experiments, the Board has deemed it important to continue the experiments on a larger scale,

and an experimental filter has accordingly been established by the Board at Provincetown. This filter, having a superficial area of one three-hundredth of an acre, was completed and first operated near the end of December, 1896, so that no extended series of analyses showing the results of its operation are as yet available; but the experiments thus far made with this form of filter indicate that a very satisfactory purification of the water will be effected at a moderate cost.

During the summer the attention of the Board was called to the existence of several cases of typhoid fever among the inhabitants of a portion of one of the cities in the State supplied with water from a pond. Upon examination, it appeared that the pond was exposed to pollution from a picnic grove in the vicinity of the water works intake. At about the same time several cases of typhoid fever in another city were traced to a similar resort upon a large pond, which, in this case, was not used as a source of public water supply by a city or town, but visitors were supplied with water for drinking, which was drawn from the pond in the vicinity of the place where sewage entered it from the buildings upon the grounds.

Summer resorts of this kind have become quite numerous in the State, especially in recent years, with the extension of electric railroads; and, in view of the bad sanitary conditions found in the two places referred to, the Board has caused an investigation to be made of a large number of such resorts throughout the State. It is proposed to continue this investigation, and, in cases where the source of water supply and the sanitary conditions are unsatisfactory, to secure their improvement, so far as possible, through owners and the local authorities.

The problem of purification of manufacturing refuse has received special attention, and much valuable information has been obtained from experiments with reference to the purification of sewage of this character, the results of which are given in detail in subsequent pages of this report. Tanneries, paper mills and wool-scouring mills are prominent among the manufacturing establishments which produce large quantities of manufacturing sewage, and a large establishment of either of these kinds may produce as much sewage as a large town, and the organic matter in the sewage of some of these establishments may be several times as great as in an equal volume of domestic sewage. The chemical analyses of manufactur-

ing sewage have shown that in some cases the chemicals used in manufacturing processes are of such a kind as would destroy nitrification if the sewage should be applied to an ordinary sewage filter directly as it comes from the factory. Ordinary methods of chemical precipitation also have little effect upon some kinds of manufacturing sewage. A summary of the results of the investigations made during the year is presented in subsequent pages of this report.

Investigations as to the purification of sewage and water at the Lawrence Experiment Station have been continued as in previous years, and in connection with these investigations a large number of samples of sewage and effluent from existing sewage disposal works has been examined. The results obtained from the experiments with filters which have now been in use for several years are of much value in furnishing information as to the permanency of sewage filters of various materials and the best means of maintaining their permanency, especially in view of the increasing number of sewage-disposal plants in the State and the increasing demand for sewerage facilities.

The Lawrence city filter, established in 1893, continues to operate satisfactorily, and the mortality from typhoid fever in the city of Lawrence is the lowest that has occurred for many years, as indicated by the table on a subsequent page.

ADVICE TO CITIES AND TOWNS.

Under the provisions of chapter 375 of the Acts of 1888, entitled "An Act to protect the purity of inland waters, and to require consultation with the State Board of Health regarding the establishment of systems of water supply, drainage and sewerage," the Board is required

"from time to time to consult with and advise the authorities of cities and towns, or with corporations, firms or individuals either already having or intending to introduce systems of water supply, drainage or sewerage, as to the most appropriate source of supply, the best practicable method of assuring the purity thereof or of disposing of their drainage or sewage, having regard to the present and prospective needs and interests of other cities, towns, corporations, firms or individuals which may be affected

thereby. It shall also from time to time consult with and advise persons or corporations engaged or intending to engage in any manufacturing or other business, drainage or sewage from which may tend to cause the pollution of any inland water, as to the best practicable method of preventing such pollution by the interception, disposal or purification of such drainage or sewage; provided, that no person shall be compelled to bear the expense of such consultation or advice, or of experiments made for the purposes of this act. All such authorities, corporations, firms and individuals are hereby required to give notice to said Board of their intentions in the premises, and to submit for its advice outlines of their proposed plans or schemes in relation to water supply and disposal of drainage and sewage; and all petitions to the Legislature for authority to introduce a system of water supply, drainage or sewerage shall be accompanied by a copy of the recommendation and advice of the said Board thereon."

During the year 1896 the Board has given its advice to the following cities, towns, corporations and individuals who have applied for such advice under the provisions of the general act of 1888, or under special acts relating to water supply and sewerage.

Replies were made during the year to applications made from the following sources for advice relative to water supply: Acton, East Acton, Ashland, Braintree (two replies), Cohasset, Franklin, Harvard (Hildreth Bros.), Hatfield, Haverhill (Real Estate Improvement Company), Huntington, Hyde Park Water Company, Kingston, Massachusetts School for the Feeble-minded, Medfield Insane Asylum, Medway, Medway Water Company, Merrimac, Montague (Miller's Falls), Northampton, Pittsfield, Plymouth, Revere Water Company, Sheffield Water Company, Swampscott (Marblehead Water Company) two replies, Uxbridge, Ware, Wellesley, Williamsburg and Woburn.

Replies were made during the year relative to sewerage and sewage disposal, in answer to applications from the following sources: Agawam, Attleborough, Brockton (two replies), Danvers, Danvers Lunatic Hospital, Metropolitan Sewerage Commission (four replies), Natick, Springfield, Stockbridge, Taunton (four replies), Van Choate Electric Company of Foxborough, Westborough Insane Hospital and Whitman.

Replies were also made to the authorities of certain cities and towns, relative to the pollution of streams, as follows: to the water board of Bradford, the water board of Ipswich, the select-

men of Manchester, the board of health of North Adams, the selectmen of Northfield, the water board of Peabody, Mr. U. W. Boyden of Walpole (the Neponset Reservoir), Wrentham (Messrs. Lincoln, Bacon & Co. of Plainville), the Williamstown Water Company.

WATER SUPPLY.

The following is the substance of the action of the Board during the past year, in reply to applications for its advice relating to water supply:—

Acton. An application was received from the water committee of Acton, Nov. 8, 1895, requesting the advice of the Board relative to a proposed water supply to be taken from the ground in the west part of the town, near the boundary line between Acton and Boxborough. The Board replied to this application as follows:—

Boston, March 6, 1896.

The Board has caused an examination of the territory from which it is proposed to take the supply to be made by one of its engineers, and has analyzed samples of water sent in by you from test wells in this territory.

The analyses show that the water was soft and of excellent quality for the purposes of a public water supply at the time the samples were collected. It appears that only a small amount of water had been drawn from the wells at this time, and, though the water was of satisfactory quality, whether it will remain so when water is pumped continuously for a long time cannot be predicted with certainty with present information. Experience with ground-water supplies of the State shows that in some cases, where the water was excellent at first, iron has subsequently appeared in excessive quantities, and the quality of the water has rapidly deteriorated with long-continued pumping, until it has become necessary to provide a new supply. In other cases the waters have remained unchanged after as many as twenty years of continuous pumping, but there is no case which has come to the attention of the Board in which long-continued pumping has improved the quality of the water.

The probable quantity of water to be obtained from an underground source is necessarily somewhat indeterminate. The indications in this case, furnished by an examination of the results obtained from fourteen test wells driven in this locality, are, on the whole, unfavorable to obtaining a large amount of water from the ground here, because the stratum of water-bearing material is in some places very thin and in other places

wholly absent, and because ledge is found in some places at a depth of only 17 or 18 feet beneath the surface.

Under the circumstances, the Board does not advise the construction of works for taking a supply from this locality, unless more extended investigations and a suitable pumping test should indicate beyond reasonable doubt that a sufficient supply of water of satisfactory quality can be obtained from the ground in the locality proposed.

East Acton. An application was received Feb. 18, 1896, from citizens of East Acton, for the advice of the Board relative to the propriety of taking a supply of water from the water works of the town of Concord. The Board replied to this application as follows:—

Boston, March 6, 1896.

The town of Concord is supplied from Sandy Pond, in Lincoln, which is also the supply of the town of Lincoln. The act of the Legislature giving these towns the right to supply themselves with water (chapter 188, Acts of 1872) contains the following provision:—

Sect. 11. All the provisions of this act concerning the town of Concord shall apply to the town of Lincoln; and if, in the future, the water of said pond shall prove insufficient for both, the town of Lincoln shall be first supplied.

The capacity of Sandy Pond to supply the towns of Concord and Lincoln is limited, and, while no record of the amount of water consumed in these towns is available, calculations based upon the probable yield of Sandy Pond indicate that the consumption has probably already nearly reached its safe capacity.

The Board is, therefore, of the opinion that the capacity of the Concord water works is likely to prove insufficient for the supply of both Concord and East Acton in the near future, and, under existing circumstances, does not advise East Acton to obtain a supply from the Concord works, as proposed.

Ashland. The committee on water supply of Ashland applied to the Board, July 15, 1896, for advice relative to a proposed source of water supply for Ashland. The Board replied to this application as follows:—

Boston, Sept. 3, 1896.

The State Board of Health received from you, on July 15, 1896, an application for advice with reference to a proposed source of water supply

for Ashland. Subsequently, test wells were driven by you in the vicinity of the Sudbury River above the town, and in the valley of Cold Spring Brook, and the Board was informed that it was proposed to take the supply from a large well, to be located on the southerly side of the Sudbury River, between it and the Boston & Albany Railroad, about 1,000 feet west of the point where the railroad is crossed by Pleasant Street.

The Board has caused an examination of the proposed source of supply to be made by one of its engineers, and a sample of water from a test well, located at the point at which it is proposed to locate the well for the supply of the town, to be analyzed. The analysis shows that the water coming from the well at this time was of excellent quality for the purposes of a public water supply. It appears that only a small amount of water had been drawn from the well at the time this sample was collected, and it is impossible to predict from this analysis what the character of the water would be if a quantity sufficient for the supply of Ashland should be pumped continuously from the ground here for a long time.

With regard to the quantity of water obtainable from a well in this location, the information obtained by the test thus far made is insufficient to furnish a basis for a satisfactory estimate. The indications furnished by the test wells driven within 200 feet of the location of the proposed well are very unfavorable to obtaining any large quantity of water from the ground in this vicinity, both on account of the character of the soil, which was extremely fine, and on account of the nearness of ledge to the surface of the ground. Moreover, such indications as are furnished by the appearance of the ground about the well are not favorable to the existence of a deep layer of porous gravel of any considerable extent in this vicinity.

Under the circumstances, the Board does not advise the construction of works for taking a supply from this vicinity, unless more extended investigations by means of test wells and a suitable pumping test shall show that water of satisfactory quality is likely to be obtained from the ground in this vicinity in sufficient quantity for the supply of the town.

The Board will, upon application, advise you further with reference to a water supply when you have additional information to present.

The water commissioners of Braintree applied to BRAINTREE. the Board, July 20, 1896, for its advice relative to increasing their water supply by taking water from driven wells in the neighborhood of Little Pond. The Board replied to this application as follows: -

Boston, Aug. 6, 1896.

The State Board of Health has considered your application with reference to a proposed additional water supply for Braintree, to be taken from the ground north of the present filter gallery near the shore of Little Pond, and has caused an examination of the proposed source to be made and a sample of the water from a test well in this locality to be analyzed.

The results of the analysis show that the water is of the same general character as that of the filter gallery. An examination of the conditions about your present filter gallery, taken in connection with the temperature of the water and the character of the analyses shows clearly that the greater portion of the water entering your filter gallery comes by filtration from the pond.

From the information obtainable as to the area of the poud and its watershed, and with certain assumptions as to its storage capacity, it is found that the draft from your present filter gallery in the past two years approached quite closely the probable capacity of the pond in a very dry year. The quantity of water that can be obtained from the ground within the watershed of the pond is no greater than could be drawn from the pond direct, unless, by lowering the ground water near the border of the watershed, water may be induced to flow through the ground toward the filter gallery from beyond the limit of the superficial watershed of the pond. There is no evidence that any large amount of water will flow toward the proposed works from points outside the watershed, and consequently an extension of the collecting system, as proposed, cannot be expected to increase very materially the quantity of ground water obtainable in the vicinity of Little Pond. The construction of additional works along the shore of the pond would make it possible, by lowering the level of the ground water, to draw a somewhat greater quantity of the water stored in the ground over a larger area than at present, and probably to cause a somewhat greater amount of filtration from the pond into the ground.

The watershed of Little Pond contains a population of about 620, or about 1,100 persons per square mile, and, as there are no sewers in this territory, the water is exposed to danger of pollution from this population, so that this pond cannot be regarded as a proper source of water supply if the water is taken directly.

An examination of the results of analyses of samples of water collected from your present filter gallery from time to time shows that there has been a deterioration in the quality of the water, and in the latter part of 1895 the presence of an excessive amount of iron gave evidence that the water of the pond is only partially purified in its passage through the ground. The character of the water varies with the season, the water being better in wet than in dry seasons; but it is probable that, with a continued draft upon the filter gallery, the water will grow worse rather than better in the future.

The conditions are such that the purity of the water of the filter gallery is dependent upon the purity of the water of Little Pond, and, considering the exposure of the latter to pollution from the population upon its watershed, the source cannot be considered a safe one for drinking purposes. Moreover, there is a dense population upon the territory east of the pond, sloping toward the filter gallery, from which a portion of the water of the filter gallery is doubtless derived, and the presence of this population in its vicinity is also a menace to the purity of the water.

In view of all the circumstances, the Board does not advise a further extension of the works for collecting ground water in the vicinity of Little Pond, since neither the quantity obtainable nor the quality is likely to be satisfactory, but advises that you take the whole subject of your future water supply into consideration, with a view to securing a source from which an adequate supply of good water can be obtained to meet the reasonable needs of the town for a considerable time in the future.

It is understood that the town has the right to take water from Great Pond in Randolph and Braintree; but, since a good ground water would doubtless be more satisfactory, before deciding as to a source of supply it is very desirable to determine first whether it is not possible to obtain an adequate supply of ground water from some suitable source.

Braintree. The water commissioners of Braintree again applied to the Board, Aug. 21, 1896, for its advice relative to a "temporary arrangement" for an increase of its water supply. The Board replied to this application as follows:—

Возтом, Sept. 3, 1896.

The State Board of Health received from you, August 25, an application for advice with reference to obtaining an additional supply of water for the town by putting in tubular wells on the shore of Little Pond, near your present pumping station, in which you state that, pending action by the town with reference to the recommendations contained in the reply of the Board to a previous application, there is an urgent necessity for temporarily supplying more water to the town than can be obtained from the present filter gallery. Accompanying the application was a plan showing the proposed location of test wells along the shore of Little Pond, just north of the present pumping station, the nearest well being distant about 75 feet and the farthest 225 feet from the pumping station. As indicated upon the plan, the wells will be 17 feet from high-water mark in Little Pond.

The Board has carefully considered this scheme, and concludes that it is

probable that a larger supply could be obtained temporarily from the wells and filter gallery together than from the filter gallery alone; but, as it appears that the capacity of this pond and its watershed for supplying water to the town of Braintree in a dry year has already practically been reached, the increase of supply obtained by drawing from the wells would be only temporary, and should a dry year occur, the supply would become exhausted.

With regard to the quality of the water to be obtained from the proposed wells, it may be said that, so far as can be judged from a single analysis, the indications are that it will not differ materially from that of the present filter gallery; and, if the water entering the wells by filtration from the pond should be imperfectly filtered, as there is reason to expect that it may be, the water of the wells will be exposed to danger of pollution from the population upon the watershed of the pond. The sanitary conditions at present existing in the region in which it is proposed to locate the wells are bad, but the conditions could be considerably improved by careful sanitary care of the watershed. Considering the urgent need for an additional supply of water while you are seeking a better source of supply, the Board considers that it is permissible to obtain it in the manner proposed, if the precautions suggested are carefully observed.

Cohasset. The Cohasset Water Company applied to the Board Nov. 14, 1896, for its advice relative to an additional water supply, to be taken from the ground in the neighborhood of a small brook in that town. The Board replied to this application as follows:—

Boston, Dec. 5, 1896.

The State Board of Health has considered your application for advice with reference to obtaining an additional supply of water for Cohasset from the ground in the vicinity of a small brook west of Sohier Street, and has caused an examination of the locality to be made by its engineer, and samples of water collected by you from two of the test wells in this locality to be analyzed.

The water of both samples was found to be softer than that furnished by your present wells, but the water from one of the wells (No. 10), which is located a considerable distance south of the railroad and east of the brook, has at some time been polluted and subsequently purified by its passage through the ground. The sample from the other well (No. 7), which probably represents more nearly the average quality of the water of this region, was much softer and of better quality, and in its present state would be a more satisfactory water for domestic purposes than that furnished from your present works.

The information obtained from the tests thus far made is not sufficient to make it possible to predict with accuracy the probable amount of increase in your supply that would be obtained by the use of wells in the localities proposed. From information furnished as to the height of water in the test wells, it appears that the ground water in this vicinity is probably already influenced by the pumping from your present wells. By lowering the ground water here by means of additional wells, it would be possible to draw a somewhat greater quantity of the water stored in the ground, and to cause the water to percolate toward the wells from a larger area than at present. It is possible, also, that water from the brook filters into the ground to some extent under present conditions, and filtration from this source might be increased somewhat by lowering the level of the ground water in the vicinity of the brook; but it does not seem likely that there will be any considerable increase in the quantity of water that will be obtained from this source. It appears, from the results obtained from the test wells, that ledge is found nearer the surface at this place than in your present wells, and that the gravel stratum in most of the wells is quite thin. These indications are not favorable to a large yield from the proposed source, and are not conclusive as to whether the additional supply obtainable in this place will be sufficient to warrant the expense of connecting it with your present works, even though the cost would be small.

It is desirable, therefore, before incurring the expense of constructing permanent works in this locality, that you cause a pumping test to be made by pumping continuously from a number of wells with a steam pump for a period of at least two weeks, with a view to obtaining some more definite evidence as to the probable yield from this source. The capacity of your present works is insufficient for the present needs of the town in the summer season, and it is very desirable that in constructing additional works you secure a supply that will be adequate for present needs in a dry season and sufficient to meet the reasonable needs of the town for a considerable time in the future. Unless, therefore, you find upon further investigation that the quantity of water which these wells will furnish will be a material addition to your present supply and furnish a sufficient quantity of water to meet the needs of the town in connection with your present works for several years, it will probably be more economical to secure in the beginning a supply from some adequate source.

Franklin. The selectmen of Franklin applied to the Board, Aug. 1, 1896, requesting the Board "to investigate the sources of the public water supply of Franklin, and report their finding." The request was made on account of a communication from one of

the citizens of Franklin, asking for an investigation as to the quality of the public water supply. The Board replied to this application as follows:—

Boston, Oct. 1, 1896.

The Board has caused an examination of the sources of supply to be made and samples of the water to be analyzed. The sources in use at the time of examination were two wells, located on the easterly side of Mine Brook, distant about 50 feet from high-water mark in the brook, and a pond, known as Beaver Pond, on the westerly side of Mine Brook.

There is a large population in the village of Franklin upon the territory from which a portion of the water which enters the wells is evidently derived, but no buildings are found within 700 feet of the wells at the present time. Analyses of the water show the presence of some of the mineral matters due to the sewage entering the ground in the populated portion of the territory draining toward the wells. It is probable, also, that a portion of the water is derived by filtration from Mine Brook, a highly polluted stream; but the analyses show that such polluted waters as may have mingled with the ground water entering the wells have been thoroughly purified in their passage through the ground, and at the present time the water is safe for drinking. The indications are that the population will increase upon the territory sloping toward the wells, and in that case the quality of the water will tend to deteriorate; but if no houses are constructed nearer the wells than at present, and if the sewage is removed from the district, further deterioration can probably be arrested.

As already stated, it is probable that a portion of the water entering the wells is derived from Mine Brook by filtration through the ground. The experience with wells in similar situations has sometimes been that after a longer or shorter period of use the quality of the water deteriorates, owing to imperfect filtration of the water passing through the ground from the neighboring pond or stream to the well; and, while there is no evidence that any of the water entering the wells of the Franklin Water Company up to the present time has been imperfectly filtered, it is very desirable that the discharge of domestic or manufacturing sewage into Mine Brook or its tributaries above the wells be prevented.

The analyses of the water of Beaver Brook show that it is highly colored, and contains at times a large amount of organic matter in the form of microscopical organisms of a kind which have been known to produce disagreeable tastes and odors in the water of many other ponds and reservoirs in the State. These conditions affect the appearance and taste of the water, but with our present knowledge are not regarded as dangerous to the health of those drinking it. The watershed of the pond contains so

small a population that the danger of the pollution of the water from sewage discharged upon the ground within its watershed is very slight. From an examination of the pond and its surroundings, it appears that between the pond and Mine Brook there is an area of low and swampy land which is apparently flooded at times of high water in the brook, and the outlet from the pond to the brook passes through this low land. It is not feasible to determine, from the limited examination which the Board is able to make, whether it is possible for the water from the brook under certain conditions to enter the pond. If brook water should enter the pond, it would enter on the side where the intake is located, and there would be great danger that this polluted brook water might be drawn for the supply of the town. In order to determine whether this is possible, a careful survey and investigation will be necessary, and the Board advises that such an investigation be made. If it should be found that brook water can, under present conditions, enter the pond, it may probably be kept out by constructing a dam, and, if necessary, a dike, at the outlet of the pond and along its easterly shore; but if these works should be found necessary, it would be well to consider whether it may not be possible to obtain a more satisfactory supply than the pond furnishes, by constructing a well at some suitable locality in the vicinity of the town where a satisfactory supply of ground water can be obtained.

It is possible that a portion of the complaint as to the quality of the water supplied to the town may be due to the growth of microscopical organisms in the open tank. Trouble from this cause could be avoided by covering the tank, and it is advisable that this be done if the use of ground water is to be continued.

HARVARD. Messrs. Hildreth Bros. of Harvard applied to the Board, June 26, 1896, for advice relative to a proposed water supply for a factory and a few dwelling-houses in that town, to be taken from a well north of the common. The Board replied to this application as follows:—

Boston, Aug. 6, 1896.

The analyses show that the water is hard and has at some time been polluted, but subsequently well purified by its passage through the ground. In its present condition the water is suitable for drinking and other domestic purposes, though the hardness will probably make it somewhat unsatisfactory for washing and for use in boilers.

The information furnished by you indicates that the quantity of water which the source of supply will yield is limited, but is probably sufficient for the supply of the factory and houses mentioned in your application.

It is suggested that, should an additional supply be found necessary in the future, better results can probably be obtained at less expense by sinking wells at some place where there is a considerable area and depth of gravelly soil, and avoiding the sinking of wells in rock, if a suitable area can be found where the water will not be exposed to danger of pollution.

HATFIELD. The selectmen of Hatfield applied to the Board, May 7, 1896, for its advice relative to taking the water of Field's Brook as a supply for a portion of the town of Hatfield. The Board replied to this application as follows:—

Boston, June 4, 1896.

The analysis shows that the water is soft, practically colorless and of excellent quality for the purposes of a public water supply. Its quality would be likely to be more satisfactory to consumers if the water is stored in a reservoir from which light is excluded than if stored in an open reservoir.

The information available as to the quantity of water that the proposed source will yield in the drier portion of a dry year is not sufficient to enable the Board to advise you definitely as to whether the yield of the brook will be sufficient for the supply of the village at all times; and, considering the desirability of obtaining an ample supply and one which can be furnished under sufficient pressure for fire purposes, the Board does not at present advise the construction of works for taking water from this source, but advises a further investigation, to determine whether a more ample supply of equally good water may not be obtained at a reasonable cost, and at such an elevation above the village that the pressure in the pipes will be sufficient for use in the extinguishment of fires.

HAVERHILL (the Real Estate Improvement Company). This corporation applied to the Board, July 23, 1896, for advice with reference to the use of water from a well situated beneath a building in Haverhill, for domestic purposes. The Board replied to this application as follows:—

Boston, Sept. 3, 1896.

The State Board of Health has considered your application for advice with reference to the use for domestic purposes of water drawn from a well beneath a building in the densely populated portion of Haverhill, and has caused an examination of the premises to be made by one of its engineers and samples of the water to be analyzed.

It appears that the quantity of water furnished by the well is insufficient for the supply of the building, and to insure a full supply at all times there is an automatic connection with the city water works by means of which the building is partially supplied with city water. For this reason it is difficult to obtain representative samples of the well water. The analyses show, however, that the quality of the water is objectionable on account of its extreme hardness, the hardness being about ten times as great as that of the chief sources of the city's water supply; and it is evident from the analyses that the water entering the well has been previously polluted by sewage and subsequently largely purified by its passage through the ground, but the indications are that the purification is not perfect at all times.

Considering the location of the well and the character of the analyses, the Board does not consider this well a safe source of water supply for domestic purposes, and advises that its use be discontinued.

Huntington. The Board received an application from citizens of Huntington, Dec. 23, 1895, for the advice of the Board relative to a proposed increase of their water supply by taking the water of certain springs west of the village. The Board replied to this application as follows:—

Boston, March 6, 1896.

The State Board of Health received from you Dec. 23, 1895, an application with reference to a proposed additional water supply for the village of Huntington, in which you state that you have at present a source of supply sufficient for about forty families, but that, having in view the extension of the works, for which your present source will not furnish a sufficient quantity of water, you wish to increase your supply by obtaining water from a group of springs west of the village. In a communication accompanying the application it is stated that an application may be made to the Legislature for a charter.

The Board has caused an examination of the proposed source of supply to be made and a sample of the water to be analyzed. The analysis indicates that the water is excellent for the purposes of a domestic water supply.

The quantity of water which the proposed source would furnish cannot be estimated with accuracy with present information, but it is likely in dry seasons to be less than the yield of your present source, which was found inadequate at times during the past summer for the supply of forty families.

It is the tendency in all communities, even in very small ones, into which a public water supply has been introduced, for the consumption of water to increase rapidly for several years, and it is improbable that your present and proposed works together would supply as much water as ought to be provided for a village the size of Huntington.

The Board would, therefore, advise that you have a thorough investigation made, with a view to determining the best source for the permanent supply of the village; and it would probably be a measure of true economy to secure at once a source which will furnish an adequate supply of good water, rather than to spend money upon a source that is likely to prove inadequate in a very few years, if the pipe system in the village is extended to any considerable extent.

Should you decide to make further investigations with reference to obtaining a supply from a larger source, the Board will advise you concerning it when you shall have submitted the results of your investigations.

HYDE PARK. The Hyde Park Water Company applied to the Board, Aug. 24, 1896, for its advice relative to taking an additional supply of water from the neighborhood of Mother Brook, between Hyde Park and East Dedham. The Board replied to this application as follows:—

Boston, Dec. 3, 1896.

The State Board of Health received from you, on August 24, an application requesting advice as to obtaining an additional water supply for Hyde Park from the region in the vicinity of Mother Brook between Hyde Park and East Dedham, through which the metropolitan sewer has recently been constructed. Subsequently you made more definite investigations in this territory, by driving test wells on both sides of the brook, about 1,000 feet below the lower dam of the Merchants' Woolen Mill in Dedham, near the boundary line between Dedham and Hyde Park, and a plan showing the location of these wells has been submitted.

The Board has caused an examination of this territory to be made by one of its engineers, and samples of the water from two of the test wells, one located on the northerly and the other on the southerly side of the brook, to be analyzed.

The sample from the well on the northerly side of the brook, which was collected before any considerable quantity of water had been pumped, was found to be soft and of good quality, though there were indications that the water had previously been polluted to a slight degree by sewage and subsequently purified by its passage through the ground.

From one of the wells on the southerly side of the brook two samples

were collected for analysis, one after pumping for about eight hours and the other after pumping for about two days. These analyses showed in a much greater degree than the first the effect of previous pollution due to the presence of population upon the territory from which the water is derived, but the analyses also show that the water had been very thoroughly purified by its passage through the ground.

With regard to the probable quantity of water to be obtained from this source, the information at present available is not sufficient to enable a definite prediction to be made. The examinations thus far made indicate that water can be drawn from the test wells with much freedom, and the character of the soil south and west of the wells, judging from surface indications, is favorable to a large yield of water from the ground.

The situation of the test wells is such that it seems probable that, when a continuous draft is made upon the ground, water will be drawn from territory in Dedham and Hyde Park where there is a large population, and the water will become harder than it is at present, and it may be less perfectly purified.

Another source of danger to the quality of the water is that the water of Mother Brook, which receives a considerable quantity of domestic and manufacturing sewage from the territory through which it flows, may find its way through the ground to the wells without being thoroughly purified by filtration. It is impracticable to predict whether the water taken from the ground in this region would deteriorate in quality from either cause to such a degree as to make it unsafe for use for the next two years; but, considering the necessity of supplementing your present supply and the desirability of obtaining a water of better quality than that at present supplied to Hyde Park and Milton, for use until such time as the metropolitan water supply shall be available, the Board would advise that this location be adopted as a temporary source of supply, but that the quality of the water be carefully observed by means of frequent analyses, in order that any serious deterioration may be discovered. The wells should be located as far as practicable from dwelling-houses and from Mother Brook.

Kingston. The water board of Kingston applied to the Board, April 27, 1896, for its advice relative to increasing the public water supply by taking water from the ground in the valley of Furnace Brook in that town. The Board replied to this application as follows:—

Boston, July 3, 1896.

The State Board of Health has considered your application for advice with reference to a proposed water supply for the town of Kingston, to be

taken from the ground in the valley of Furnace Brook, so-called, and has caused an examination of the proposed source to be made by one of its engineers, and samples of water from test wells in the region in which it is proposed to locate the works to be analyzed.

Judging from tests which you have made by driving wells in the valley of the brook about 600 feet below the tack factory, and pumping from them, the conditions are favorable, both with regard to the porosity of the material and the freedom with which water could be pumped from the test wells, to obtaining a large quantity of water from the ground at this place.

The water of the test wells, as shown by several analyses, is colorless, soft, and otherwise of excellent quality for the purposes of a public water supply. The quantity of iron present in the water was insignificant, and showed no tendency to increase while pumping for a period of ten days; but there are indications that the water filtering past the dam at the tack factory is strongly impregnated with iron, and in constructing a system of wells for collecting ground water in this valley it will be necessary to avoid locating any of the wells in the vicinity of this dam.

The surface of the ground about the test wells is at an elevation several feet above your present pumping station, and it is understood that you propose to lay a pipe to convey the water from the proposed source to the pumping station by gravity; but if sufficient water is not furnished in this way it is expected to use the pipe as a suction main. It is probably not practicable, with so long a suction main, to reduce materially the level of the water in the ground about the wells; and, as the area from which water can safely be drawn is limited by the proximity of the dam above the wells and by the character of the material found beneath the ground a short distance down stream from the wells, which is said to be very fine, there is some uncertainty as to whether a sufficient quantity of water for the supply of the town at all times can be obtained from this source in the manner proposed.

It is very desirable, in constructing works for obtaining a new supply of water, that you secure an ample quantity for the needs of the town at present and for a reasonable time in the future; and the Board advises that, before finally locating your wells and laying the pipe to the pumping station, you ascertain whether the supply can be increased, if necessary, by extending the collecting system farther up the valley of Furnace Brook.

The Board is informed that there are several long lines of lead pipe in use for distributing water in the town, notwithstanding the fact that the use of these pipes for the distribution of water seriously injured the health of many citizens of the town last year, causing this Board to recommend the immediate removal of all lead pipes in the town. The Board again

urges the town to proceed at once to remove all the lead pipe now in use in the town, whether as mains or service pipes.

Massachusetts School for the Feeble-minded applied to the Board, May 21, 1896, for its advice relative to the propriety of covering their water reservoir. The Board replied to this application as follows:—

Boston, July 3, 1896.

The State Board of Health has considered your application for advice as to the necessity or advisability of covering the distributing reservoir of your water-supply system, in which you state that your supply is obtained by pumping from the works of the city of Waltham, and that the water is often offensive to sight and smell, but that it has not apparently been any better or worse for passing through your reservoir.

The water supply of the city of Waltham is taken from a covered filter basin and well near the Charles River, above the city, and the water at the source of supply is free from taste and odor and from vegetable organisms, and is a very satisfactory water for domestic use. The water is supplied to the city by pumping, and an open reservoir is used in connection with the distributing system. The exposure of the water to light in the reservoir is the cause of the presence in the water of large numbers of microscopical organisms at nearly all times, which impart to the water a disagreeable taste and odor.

The effect of exposing ground water to light in an open distributing reservoir upon the quality of the water is well known, and the use of the reservoir is avoided, so far as practicable, by pumping as nearly as possible at the same rate as the consumption. It is, therefore, probable that most of the supply that is pumped to your distributing reservoir, especially during the summer season, is water which comes from the well or filter basin, and has not passed through the city distributing reservoir. The storage of this water in a reservoir where it is exposed to light would be favorable to the growth of microscopical organisms, and the quality of the water would deteriorate in consequence.

In view of the circumstances, therefore, it is desirable that you cover your reservoir in such a manner as to keep the water wholly from exposure to the light. There will, of course, still be danger that a portion of the water pumped to your reservoir will come from the Waltham distributing reservoir, and possibly be affected by taste and odor; but if your reservoir is covered so as to exclude the light, the conditions will be unfavorable to a continuation of the development of microscopical organisms that may enter it.

Medfield Insane Asylum. The trustees of the Medfield Insane Asylum applied to the Board, July 1, 1896, for its advice relative to a proposed additional water supply for the asylum, to be taken either from driven wells near the present supply or from Farm Pond in Sherborn. The Board replied to this application as follows:—

Boston, Oct. 1, 1896.

The Board has caused an examination of both of these sources to be made by one of its engineers, and has had samples of the water analyzed. It was originally proposed to draw the supply for this institution from the ground, on the right or easterly bank of the Charles River, near the line between Dover and Medfield, and twenty tubular wells were sunk in this locality. The quality of the water furnished by these wells is excellent, but the quantity has been found to be wholly inadequate for the needs of the asylum, and the supply for purposes other than drinking has been drawn from the Charles River. Judging from information furnished by your engineer as to the character of the material found beneath the surface in this vicinity, it appears that there are in places deposits of gravel from which ground water can be drawn freely, while in other places the material is so fine that it will yield but little water. The conditions, on the whole, are such that it is not probable that a sufficient quantity of water for the asylum could be obtained by driving additional wells in the vicinity of the present works.

Farm Pond is situated at such an elevation that its water can be drawn to your present pumping station by gravity. The water of Farm Pond has been examined several times during the past summer, by means of chemical and microscopical analyses, and has been found to be very soft, nearly colorless, and otherwise of excellent quality for a domestic water supply. The watershed is free from dwelling-houses, and the source is naturally an excellent one for water-supply purposes. On one side of the pond there is a grove used by picnic parties in summer, and care will be necessary to prevent danger of pollution of the water from this cause. The situation of the pond, not far from the village of Sherborn, is such that it may be found to be the most appropriate source of supply for this village in the future; but the yield of the pond will be sufficient both for the asylum and for the town of Sherborn, unless the population in either shall increase to a much greater extent than is to be expected at present.

The Board therefore concludes that Farm Pond is an appropriate source of additional water supply for the Medfield Insane Asylum.

MEDWAY. The water supply committee of Medway applied to the Board, May 23, 1896, for its advice relative to the introduction of a public water supply, certain alternative sources being specified in the application. The Board replied to this application as follows:—

Boston, July 3, 1896.

The State Board of Health received from you, on May 25, an applicacation for advice with reference to a proposed water supply for the town, in which you mention three proposed sources of supply, two of which are in the valley of Chicken Brook and the third on the north side of Main Street, near Holliston Street.

The Board has caused an examination of the proposed sources to be made by one of its engineers, and samples of water from a spring and test well in the valley of Chicken Brook to be analyzed. The analyses show that the water is of suitable quality for domestic purposes, but it does not appear probable that a supply of ground water sufficient for the supply of the town of Medway can be obtained from the valley of this brook in the vicinity of either of the points indicated by you.

With reference to the third source, it is understood that your committee has already concluded that the probable quantity of water that could be obtained from it would be entirely inadequate for the supply of the town.

The Board has already, on a previous occasion, considered the question of a water supply from these sources and from certain other sources in the town, in response to an application from H. V. Mitchell and others, who were about to form a water company; and a copy of the reply of the Board, which was dated March 1, 1892, is enclosed.

The Medway Water Company submitted an application to this Board, in July of last year, for advice with reference to a water supply to be taken from the ground in the easterly part of the town, and have continued their investigations during the earlier portion of the present year. In response to their application, the Board has recently advised the Medway Water Company with reference to their proposed water supply, and a copy of this communication is also enclosed.

Medway. The Medway Water Company applied to the Board, July 19, 1895, for its advice relative to taking a public water supply from the ground on the left or northerly bank of the Charles River in the east part of the town. The Board replied to this application as follows:—

Boston, July 3, 1896.

The Board caused an examination of the proposed source of supply to be made, and samples of water from the test wells located in the vicinity of the corner of Walker and Village streets to be analyzed. The results of these analyses showed that the water had previously been polluted and subsequently purified to a large extent by its passage through the ground; but iron was present in such quantities in some of the samples as to indicate that the water would be affected by the presence of an excessive amount of this ingredient, should a large quantity of water, such as would be needed for the supply of the town of Medway, be drawn continuously from the ground in this vicinity.

In view of the unfavorable character of the water obtained from these test wells, you requested that the Board postpone the consideration of this matter until further investigations could be made; and in the spring of the present year a second group of test wells was put in by you in territory on the opposite side of the river, and about 500 feet farther down stream. These wells are three in number, and are situated about 60 feet from the river, where the latter makes a sharp bend known as the "ox-bow." The Board has caused an examination of this locality also to be made, and has found that the conditions, as regards the porosity of the soil, are favorable to obtaining water freely from wells here, and the territory on both sides of the river appears to be of a porous character, judging from surface indications; but with the information at present available it is not feasible to tell whether or not a sufficient supply of water for the town can be obtained from the ground in this vicinity.

Samples of water have been collected from each of the three test wells on two occasions, and the results show in general that the water has at some time been polluted but subsequently purified by its passage through the ground. The quantity of iron in all of the samples was so small as not to affect the quality of the water, but there was a marked increase in the quantity of iron found in the second set of samples, which were collected after pumping for about ten hours daily for several days with a hand pump. The quality of the water in other respects improved somewhat with pumping.

The changes that took place in the character of the water while pumping only a comparatively small amount from the wells make it impossible to predict what the probable character of the water would be, after pumping continuously for a long time a quantity such as would be needed for the supply of Medway. The location of the proposed wells, in the vicinity of Charles River, a stream which receives considerable sewage pollution from the factories and villages along its banks above this point, makes it essential that any water that may enter the wells from the

river shall be thoroughly purified by filtration for a long distance through the ground.

In view of all the circumstances, the Board does not advise the construction of works for taking a supply of water from the ground in the vicinity of the present test wells until you have made further tests by driving wells and pumping from them continuously, at as great a rate, at least, as would be necessary for the supply of a town like Medway, and for a sufficient time to determine whether this source can be depended upon to furnish water of satisfactory quality for drinking purposes, and in sufficient quantity for the supply of the town.

It is very desirable, in putting in additional wells, that they be placed at a much greater distance from the river than the present test wells.

The Board will, upon application, give you further advice in this matter when you have the results of further investigations to present.

MERRIMAC. The water supply committee of Merrimac applied to the Board for its advice relative to a water supply for that town, suggesting certain sources for examination. The Board replied to this application as follows:—

Возтом, Dec. 3, 1896.

The State Board of Health has considered your application with reference to a proposed water supply for the town of Merrimac, and has caused an examination of the sources mentioned in your application to be made by its engineer, and samples of the waters to be analyzed.

The first source mentioned is Cobbler's Brook, which you propose to use either by taking water from the ground, about half a mile above the railroad station and near the old Tukesbury dam, or by taking water from a storage reservoir, to be formed by constructing a dam across the valley near the old Tukesbury dam, or by both methods.

In this locality you have made tests of the ground by means of tubular wells, a portion of the wells being located close to the old dam, and the others about 400 feet farther down the stream. The results of these examinations do not show the presence of porous material of sufficient depth and extent to furnish a reasonable expectation of obtaining any considerable quantity of water from the ground. An analysis of a sample of water collected by you from the test well from which water could be pumped with the most freedom, shows that it contains so large a quantity of iron that the water would be objectionable for many domestic purposes.

It is probable that, by constructing a storage reservoir of sufficient size at the place proposed, enough water could be obtained from the brook for the supply of the town; but the analyses of samples of water from the

brook at this point show that the water is highly colored and contains a large amount of organic matter, so that it would be an unsatisfactory water for domestic uses in its present state, and it is unlikely that its quality would be materially improved by storage in a reservoir of the size that would be needed for the supply of the town of Merrimac.

The next source mentioned in your application is Lake Attitash, or Kimball's Pond, water to be taken either directly from the pond or from the ground near the pond, or by both methods.

The pond is capable of supplying a much greater quantity of water than would be needed by the town of Merrimac. A limited number of analyses of the water, made in the months of May, September and October, show that it is soft, but that its quality is variable. The water has at times a high color and contains a somewhat large amount of organic matter, as shown by these analyses; and the microscopical examinations show the presence of some minute vegetable organisms, which are often found in waters which give trouble from bad tastes and odors. The pond is, moreover, exposed to danger of pollution from the summer cottages along its shores, and in its present condition cannot be considered a desirable or safe source of public water supply.

Test wells have been driven by you in two localities in the vicinity of the pond, one near the southerly shore and the other near the westerly shore south of Back River. The results obtained from tests near the southerly shore of the pond were unfavorable, since no deep stratum of coarse sand or gravel was found from which water could be obtained with freedom. The tests made on the westerly shore of the pond were somewhat more favorable, and a sample of water collected by you from one of the wells was found to be colorless, soft, and otherwise excellent for the purposes of a water supply; but ledge was found at no great distance beneath the surface, and, judging from the results of these tests, the conditions are not favorable for obtaining a sufficient quantity of water for the town in this locality.

The next source mentioned is "The Plains," so-called, a level tract of land extending from near the southerly end of Kimball's Pond toward the Merrimac River. From information obtained from a single test well as to the character of the material beneath the surface of the Plains, it appears probable that the material is too fine to yield water freely in any considerable quantity; and, judging from the topography of the region, the area from which water would be contributed to the wells in this territory would be too small to furnish at all times the quantity of water that would be required by the town.

The last source mentioned in your application is the Back River watershed, from which you propose to take water either from the ground just below and not far from Sargent's Millpond, including the water of Sargent's Spring, or directly from the brook by constructing a storage reservoir thereon, or by both methods.

It appears that three test wells have been driven in this valley, at points within a distance of about a quarter of a mile below Sargent's Pond, in two of which the material was found to be so compact that no water could be obtained, and ledge was found within a few feet of the surface. In one of the wells a coarse stratum of gravel was found, from 6 to 14 feet beneath the surface, from which water could be drawn with considerable freedom, and a sample of water from this well was collected by you for analysis. The results showed the presence of so large a quantity of iron in the water as to make it very objectionable for most domestic uses.

Sargent's Spring and the springs in its vicinity, according to measurements furnished by your engineer, would not, alone, furnish a sufficient quantity of water for the town, though the quality, judging from an analysis of the water of one of these springs, would probably be good.

Analyses of the water of Back River show that it is very highly colored and much poorer in quality than the water of Cobbler's Brook, so that its use for water-supply purposes would be even more objectionable than the use of water from Cobbler's Brook.

From the investigations thus far made, it does not appear that any of the sources mentioned in the application are likely to furnish a sufficient quantity of water of satisfactory quality for the supply of the town of Merrimac.

In general, a supply of water taken from the ground is much to be preferred to one taken from a stream or other surface-water source, because the water is colorless and free from unpleasant tastes and odors; and the Board would advise that you continue your investigations, with a view to obtaining a supply of good water from the ground.

While the investigations made in the vicinity of Kimball's Pond were unfavorable to obtaining a sufficient supply of water from the ground, they were not extensive enough to enable the Board to conclude that a sufficient supply may not be obtained in this region. Judging from surface indications, coarse gravel is likely to be found beneath the surface along the northerly side of Kimball's Pond, between its outlet and Back River; and, while this territory is outside the limits of Merrimac, it is desirable that an investigation be made here, to see whether it may not be possible to obtain a supply of water from the ground in this locality. It also seems desirable that a further investigation be made along the shore of the pond, south of Back River.

The Board will, upon application, give you further advice in this matter when you have the results of additional investigations to present.

Montague (Miller's Falls). The State Board of Health received an application from the water supply committee of Miller's Falls, Dec. 9, 1895, for the advice of the Board relative to certain proposed sources of water supply for that village, at the same time suggesting Osgood Brook and Lake Pleasant as alternative sources. The Board replied to this application as follows:—

Boston, Feb. 6, 1896.

The State Board of Health has considered your application with reference to a proposed water supply for Miller's Falls, in which you state that the sources under consideration are Osgood Brook, so-called, and Lake Pleasant, the present source of supply of Turner's Falls, and ask the advice of the Board as to which of these sources will furnish the best water, and as to whether Osgood Brook will furnish enough water, if taken in the vicinity of Lyon's mill, to supply the present and prospective population of the village in the driest time in a dry year, and for any other information which will assist you in the selection of a water supply for the village.

The Board has caused an examination of Osgood Brook to be made, and samples of the water of the brook in the vicinity of Lyon's mill and of the water of Ruggles Pond, situated upon the brook above Lyon's mill, to be analyzed. The samples were collected from each source December 8 and 19. The water of the pond and brook on the first date had a very high color; on the second date, the color of the water of the pond remained practically the same, but the color of the water of the brook was considerably less, a condition which might have been caused by melting snowwater entering the brook below the pond.

It is difficult to judge, from analyses made at this season of the year, what the character of the water may be at other times; but, judging from the information at present available as to the character of this pond and from the results of the analyses, the indications are that the water of this pond and consequently of the brook below is likely to be unsatisfactory for domestic purposes.

While it might be possible, either by making improvements in Ruggles Pond and its vicinity by removing the vegetable matter and raising the dam or by draining the pond and the swamps above it, to improve the quality of the water of Osgood Brook, the cost to the village of obtaining a water supply of satisfactory quality in this way would probably exceed the cost of a supply from Lake Pleasant.

With reference to the probable quantity of water that Osgood Brook would furnish in a very dry season, without the use of the storage capacity of Ruggles Pond, no definite advice can be given with present informa-

tion. Should the flow per square mile be as small as has been found to be the case with some brooks of similar character, the yield would not probably be sufficient for the village at all times; while, if the flow is as well maintained in the drier portion of a dry summer as it is in the case of many other brooks, the quantity would be ample. This matter could only be determined by careful gaugings of the flow of the brook in the drier portion of a dry season.

In view of all the circumstances, the Board is of the opinion that Lake Pleasant would prove a more satisfactory source of supply than Osgood Brook in its present state, and is the more appropriate supply for the village of Miller's Falls.

Northampton. An application was received from the water board of Northampton, Feb. 3, 1896, for the advice of the State Board of Health relative to increasing the water supply of the city by taking the water of Ashfield or Bradford Brook, a tributary of Mill River. The Board replied to this application as follows:—

Boston, March 6, 1896.

The State Board of Health received from you, Jan. 25, 1896, an application relative to the use of Mill River and its tributaries as a source of water supply for Northampton. Regarding this source of supply and the proposed method of utilizing the water from it, you make the following statement:—

- "We ask for the State right to use Mill River and its tributaries for a water supply for Northampton, Mass.
- "We do not expect to use the whole system at present, but a tributary of Mill River, called the East Branch of Ashfield or Bradford Brook, in Williamsburg, which is the site of an old reservoir that went out in May, 1874, causing the Mill River flood, and which has not been rebuilt. The land flowed would be about 108 acres, the depth at dam about 47 feet, the average depth about 20 feet, the capacity about $\frac{3}{4}$ billion gallons. It is said to have filled four times in ordinary years.
- "Under the circumstances, perhaps it would be considered necessary for you to examine only this branch of Mill River.
- "The surrounding country is uninhabited, mountainous and mostly wooded, with no highways near, and no danger of pollution either present or in prospect.
- "The bed of the reservoir site is covered with a growth of wood twentytwo years old. The soil is gravelly, with no swamps so far as we know. The quality of water is excellent.

"We propose to pipe from the dam about 4 miles to where the water will flow in an open stream to our new or middle reservoir, about 2 miles."

The Board has caused an examination of the East Branch of Ashfield or Bradford Brook to be made, and a sample of water collected near the site of the former reservoir to be analyzed. The analysis shows that the water is slightly colored, but that it is quite soft, and otherwise of satisfactory quality for the purposes of a domestic water supply; and, while it is difficult to judge from a single analysis at this season of the year what the quality of the water may be at other seasons, there is little reason to expect that it would be very different; and, if the water is stored in a reservoir properly prepared for the purpose by the removal of all the soil and vegetable matter from the area to be flowed, its quality should not deteriorate.

The quantity of water which this source would yield with a reservoir of the size proposed would be sufficient, in connection with present sources, for a population several times as great as is now contained in Northampton.

An estimate of the capacity of the present sources of supply of Northampton, based upon the area of the watershed, as measured from the topographical map of the State, and the capacity of the existing storage reservoirs upon this watershed, as given in the annual reports of your board, indicates that, if the consumption of water per capita in Northampton is no larger than in other cities where records of the consumption of water are kept, the capacity of your present sources is sufficient for the supply of the city for several years, and there is no immediate need of a new supply on account of the quantity of water.

The quality of the water, while affected somewhat by contact with vegetable matter in swamps, which gives it at times considerable color, is satisfactory, excepting that the water of the reservoir recently built was affected by a disagreeable taste and odor during the summer of 1895. This may have been caused by the flooding of a swampy area adjacent to the reservoir, in consequence of the use of the flashboards upon the dam. By avoiding this condition in the future, the quality of the water of this reservoir is likely to be more satisfactory.

If the storage capacity upon the watershed could be doubled, a large increase in the capacity of the works would be made, and the need of an additional supply from another watershed would be postponed for many years. Moreover, if a site can be found where a storage reservoir of considerable depth can be constructed, and if the reservoir is properly prepared for the reception and storage of water by the thorough removal of the soil and vegetable matter from its bottom and sides, water of satisfactory quality should be obtained. It is possible that the further improve-

ment in the quality of the water could be made by draining the swamps upon the watershed, where necessary. The information at present available, however, is not sufficient to enable the Board to determine whether it is feasible to increase further the reservoir capacity upon the watershed, and it would be very difficult to make a satisfactory investigation with reference to this matter at this season of the year.

Under the circumstances, the Board would advise that, before proceeding to take an additional supply from the valley of Mill River, as proposed in your application, you cause an investigation of the watershed of Roberts' Meadow Brook to be made, to determine the feasibility of increasing the storage capacity thereon, and the probable cost of increasing the supply of Northampton in this way, as compared with the cost of obtaining an additional supply from the valley of Mill River.

In this connection the Board would also suggest that you cause an investigation to be made as to the feasibility of obtaining an additional supply in connection with your present works, by diverting into the watershed of Roberts' Meadow Brook by gravity the waters of the upper portion of the North Branch of the Manhan River, about 3½ miles above the village of Loudville, and as to the probable quantity and quality of water to be obtained from this source, and its cost as compared with the other schemes.

The Board will, upon application, advise you further in this matter when you have additional information to present.

PITTSFIELD. The board of public works of Pittsfield applied to the State Board of Health, Nov. 18, 1895, for its advice with reference to increasing the water supply of the city by taking the waters of certain brooks in neighboring towns. The board replied to this application as follows:—

Boston, Jan. 16, 1896.

On Nov. 18, 1895, the State Board of Health received from you an application for advice with reference to your proposed plans for increasing the water supply of Pittsfield, as follows:—

"The city of Pittsfield, represented by its board of public works, desires the advice of the State Board of Health upon its plans for increasing its water supply in the following manner:—

"Taking and appropriating the waters of Sachem and Hollow brooks in Lanesborough and in Hancock, if their watershed extends into the town of Hancock, and bringing them into the northern part of our water system by means of the construction of a dam or dams at a suitable elevation to cause these waters to flow into our system by gravity; the taking and appropriating of the waters of Smith and May brooks in the city of Pittsfield and the town of Hancock, and bringing them into the western portion of our water system in the same manner; raising the dam at Ashley Lake, our present storage reservoir, so as to increase its storage capacity."

Subsequently a report of your engineer was submitted, containing the results of his investigations with reference to an additional water supply for the city, with data as to the consumption of water and the flow of many streams in the vicinity, including those at present used for the supply of the city and those proposed as sources of additional supply.

The Board has caused an examination of the proposed sources of supply to be made by one of its engineers, and samples of the water to be analyzed.

The results of analyses of samples of water from each of the brooks mentioned in your application, collected by you on Aug. 12, 1895, and of samples collected on Nov. 27, 1895, after heavy rains, indicate that the water of Smith and May brooks is of about the same character as that of Sackett, Ashley and Mill brooks, three of your present sources of supply. waters of Sachem and Hollow brooks, however, while of much the same quality in most respects, are harder, the hardness of Sachem Brook apparently being nearly as great as that of Hathaway Brook, one of your present sources of supply. The hardness of the water is due to limestone, of which there appears to be a large amount within the watersheds of Sachem and Hollow brooks. On the whole, the indications are that the waters of these brooks may be much harder than is desirable for domestic use.

With regard to the quantity of water that your sources of supply could be depended upon to yield in a dry year after development in the manner proposed, no definite prediction can be made with the information at present available to the Board. The information obtained from the report of your engineer as to the flow of the various brooks during a portion of last summer and fall indicates that in a very dry year the yield of your present sources, viz., Sackett, Ashley, Hathaway and Mill brooks and Ashley Lake, might be increased from fifty to sixty per cent. by the addition of Sachem, Hollow, May and Smith brooks, as proposed. As to the question of raising the dam at Ashley Lake two feet, the experience of the past seventeen years, in five of which the lake failed to fill in the spring, shows with sufficient conclusiveness that with present conditions but little benefit can be derived from raising the dam. If, however, the area of the watershed can be increased, it may be desirable to raise the dam.

Your present sources appear to be capable of supplying the city for the next two years, even if they are dry ones, if the consumption of water is kept within reasonable limits, unless Ashley Lake fails to fill in the coming spring. In any case, should an emergency arise, a temporary additional supply, sufficient in quantity, is available by pumping water from Sackett Brook at your present temporary pumping station, though it is desirable to avoid the use of this water, if possible, on account of its excessive hardness. In view of all the circumstances, the Board would advise that you make surveys and investigations in the vicinity of Ashley Lake, to determine whether it is feasible to increase the area of its watershed and how large an additional area of watershed can be made tributary to the lake.

A few years ago the Board advised that West Pond in Washington was not a satisfactory source of water supply, on account of its color and organic matter. These are evidently derived from the vegetable matter of the swamp in and around the pond; and, in view of the fact that your present supply from Mill Brook can be readily supplemented by gravity from Roaring Brook below West Pond, and of the importance to your water-supply system of additional storage-reservoir capacity, it is worthy of examination to determine whether such reservoir capacity may not be obtained and a large drainage area made available by removing the vegetable matter in and around this pond.

It is also suggested that the question of the cost of taking water from Onota Lake by means of a pumping station at its southerly end be investigated.

In connection with these investigations, it is advisable to have the waters of the different available sources analyzed from time to time, so as to determine their general character at different seasons of the year.

With information as to the points mentioned, the Board can advise you more definitely as to the most appropriate source of additional supply for Pittsfield.

PLYMOUTH. The water commissioners of Plymouth applied to the Board, Dec. 10, 1895, for its advice relative to the best method of preventing the bad taste of their water supply, supposed to be due, as stated in the application, to the presence of *Uroglena* in the water of the source of supply (Little South Pond). The Board replied to this application as follows:—

Boston, May 7, 1896.

The State Board of Health has considered your application for advice as to whether there is any means of preventing the appearance in Little South Pond of the organism *Uroglena*, which imparts to the water a disagreeable taste and odor, and your request for advice in general as to the best method of improving the quality of the water supply of the town.

The organism Uroglena was first observed by the biologists of the Board

in the winter of 1891-92, when its presence was discovered in the water of Little South Pond and in two or three other sources at about the same time. Since then it has been observed in several other water supplies in the State, in some of which it has caused serious trouble, as at Plymouth.

The cause of the appearance of this organism in water is not known, and there is no known method of preventing its appearance or growth in the water of a pond or reservoir. In ponds in which its presence has been noted the experience has been that it occurs in the winter season, between October or November and March or April. In some ponds it has been present in nearly every year since it was first observed, though it appears to be present in less numbers and to affect the character of the water less seriously in some years than in others.

This has been the case in Little South Pond, where the organism has been present in greater or less numbers during nearly every year in the past five years, while previous to that time the water is said to have been excellent for many years. There is, however, a reference to complaint as to the quality of the water in the report of the Plymouth water board for 1877, but the exact cause of the trouble at that time does not appear to have been determined.

With reference to the best method of improving the quality of the water supply of the town, with the information at present available, the Board can advise you only in a general way.

The conditions in the vicinity of the ponds from which your present supply is drawn appear to be very favorable—judging from surface indications—to obtaining water from the ground with freedom, and this is true also of much of the territory about Plymouth. A good ground water, if delivered to consumers without exposure to light either at the source or in a distributing reservoir, is more satisfactory than a surface water, on account of its attractive appearance and freedom from taste and odor. If such a supply can be obtained in the vicinity of Little South Pond, in sufficient quantity to furnish all the water needed by the town at times when the quality of the present sources is unsatisfactory, the present conduit pipes might be used to convey the water by gravity to the pumping station and the town, as at present; and under the circumstances it would probably be more economical to take a supply from this vicinity rather than elsewhere.

If a ground-water supply is introduced, it will be necessary to make such changes in the distributing system as will make it possible to deliver water to consumers without exposure to light.

It might be possible to purify the water drawn from Little South Pond by filtration near the present pumping station, but such experiments upon the filtration of this water as have thus far been made have not been sufficient to enable the Board to advise you as to the size of filter or the rate of filtration by which the purification of the water could be satisfactorily effected. If, as a result of experiments, it should be found that it is feasible to purify the water by filtration, it is not unlikely that the cost would, in the end, be greater than the cost of a ground-water supply, if a suitable source can be found near Little South Pond, as suggested. The trouble with the water has generally been most serious in cold weather, when much care might be necessary to secure satisfactory results by filtration; moreover, while the water supplied to the high-service system might be filtered and supplied to the pumps, as at present, by gravity, pumping might be necessary in order to supply the low-service system under satisfactory pressure, on account of the loss of head in the process of filtration.

Another method by which a water of satisfactory quality might be obtained would be to extend the present intake pipes around Little South Pond to connect with Great South Pond, making it possible to draw water from either source independently by closing the connection between the ponds. While it does not appear, from the limited number of examinations thus far made, that *Uroglena* has ever been present in the water of Great South Pond, it cannot be predicted that the organism may not appear in the future in this source as well as in Little South Pond, and at the same time. It is not certain, therefore, that a water of satisfactory quality would be obtained by this method at all times.

In view of all the circumstances, the Board would advise that you have an investigation made, to determine whether it is feasible to obtain a satisfactory ground-water supply from the vicinity of Little South Pond in connection with your present works, taking into consideration the necessity

of keeping the water from exposure to light.

Before deciding to introduce a ground-water supply from the vicinity of Little South Pond, it is desirable that you determine whether the capacity of the present sources is sufficient for a considerable time in the future. If the capacity of present sources exceeds but little the present consumption of water by the town, it will probably be best to consider also the question of an additional supply, in connection with the question of obtaining a water of better quality.

The Board will, upon application, advise you further with reference to improving the quality of your water supply when you have additional infor-

mation to present.

REVERE WATER COMPANY. The Revere Water Company applied to the Board, Nov. 9, 1895, for its advice relative to increasing their water supply by taking the water of a branch of Crystal Brook,

which flows from Castle Hill in Saugus, and also as to the quality of the brook which flows past the pumping station in Cliftondale.

A subsequent application was made, Feb. 20, 1896, for the advice of the Board relative to taking an additional supply from wells in the valley of the same brook, at its junction with Crystal Brook, near the corner of Main and Harvard streets in Saugus.

Boston, March 6, 1896.

On Nov. 9, 1895, the State Board of Health received from you an application with reference to the use of water for the supply of the towns of Revere and Winthrop from the tributary of Crystal Brook, flowing from the vicinity of Castle Hill in Saugus, and from the brook flowing past your present pumping station at Cliftondale. You propose to use the water during the winter season, and to allow the ground water of your present sources to accumulate for use in the summer season. Subsequently, a further request was received for advice as to procuring an additional supply from wells at a point in the town of Saugus near the corner of Main and Howard streets, which is in the valley of Crystal Brook, near the point where it is joined by the brook flowing from Castle Hill.

The towns of Revere and Winthrop are included in the metropolitan water-supply district, works for the supply of which are now being constructed, but it is not expected that these works will be in operation for two years.

The water of the wells at Revere has always been hard, but in the last three years, owing to an excessive drought, has been affected in an increasing degree by the infiltration of sea water, and it is desirable to avoid the use of this water entirely for the present. If pumping from these wells is avoided, the water will probably return to its former condition, but it is uncertain how long a time it will require. Under the circumstances, an additional temporary supply, capable of yielding about 500,000 gallons per day during the months from June to September, inclusive, and a less amount in other months, is needed.

The Board has caused an investigation of the proposed sources of supply to be made by its engineers, and samples of the water of the brooks mentioned in the application to be analyzed.

While the water of all of the brooks is colored to a greater or less degree by contact with vegetable matter in swamps, if the water were safe for drinking, it would undoubtedly be much more satisfactory for domestic use than the water of your wells at Revere, in its present condition.

The watersheds of both of the main tributaries of the brook flowing past the pumping station at Cliftondale contain a large population, and the danger of pollution entering the stream from this population makes the water of these brooks, and consequently of the main brook, as a whole, unsafe for drinking. The watershed of the tributary of Crystal Brook, flowing from the vicinity of Castle Hill, contains a smaller population per square mile than the others, but the danger of the pollution of the water from this population is such that this brook also must be considered unsafe for drinking.

With regard to your second question, as to the advisability of procuring an additional supply of water from wells near the corner of Main and Howard streets, in the valley of Crystal Brook, in Saugus, no definite advice can be given, in the absence of any tests to indicate the probable quantity and quality of ground water to be obtained there. While Crystal Brook would not be a suitable source from which to take directly a supply of water for drinking, the use of water drawn from wells in the valley of the brook as a temporary source of supply would not necessarily be objectionable; and it may be said that the general conditions for obtaining an additional supply of water appear to be more favorable in the valley of this brook than elsewhere in the vicinity of your present works.

The Board would, therefore, advise that an investigation be made, with a view to determining the probable quantity and quality of water to be obtained from the ground in the valley of Crystal Brook in the vicinity of Howard and Main streets in Saugus.

The Board will, upon application, advise you further with reference to this source when you have additional information to present.

It has not been considered necessary, within the scope of this communication, to consider the provisions of chapter 400 of the Acts of 1893.

SHEFFIELD. The Sheffield Water Company applied to the Board, April 17, 1896, for its advice with reference to taking the water of the brook flowing from Three Mile Pond as a source of public water supply. The Board replied to this application as follows:—

Boston, June 5, 1896.

The State Board of Health has considered your application relative to a proposed water supply for Sheffield, to be taken from the brook, flowing from Three Mile Pond, known as Iron Work Brook, and has caused an examination of the proposed source to be made by one of its engineers, and samples of the water to be analyzed.

The chemical analyses show that the water is hard, and has a high color probably during most of the year; and, while it is probable that a sufficient supply for the town could be obtained from this source, the water cannot be regarded as of satisfactory quality for the purposes of a public water supply.

In reply to your application of last year, for advice with reference to the use of water from springs in the valley of Pool Brook, the Board stated that it regarded this source as an appropriate one from which to take a supply of water for the town. A second examination of the water of this source, by means of a chemical analysis in May of the present year, tends to confirm the opinion expressed last year, — that the water of the springs is soft, and of excellent quality for the purposes of a public water supply.

Judging from present information, it does not appear to the Board that there would be any material difference in the cost of works for taking water from either of the sources proposed; and, considering the excellent quality of the water of the springs in the vicinity of Pool Brook, the Board regards this source as the more appropriate one from which to take a supply of water for Sheffield.

SWAMPSCOTT. The Marblehead Water Company applied to the Board, Aug. 1, 1896, for its advice relative to an increase of their water supply by taking water from the ground in the neighborhood of Thompson's Meadow in the north part of Salem, near the boundary line between Salem and Swampscott. The Board replied to this application as follows:—

Воѕтом, Sept. 3, 1896.

The State Board of Health has considered your application for advice with reference to an additional water supply for Swampscott and Nahant, to be taken from the ground in the vicinity of Thompson's Meadow, so called, situated in the southerly portion of Salem, very close to the boundary line between Salem and Swampscott, and has caused an examination of the proposed source of supply to be made, and samples of the water from test wells in the meadow to be analyzed. The analyses show that the water is somewhat hard, but is otherwise of excellent quality for the purposes of a public water supply. Whether it will remain so if water is pumped continuously from the ground here for a long time cannot be foretold with certainty from a single examination.

Information furnished by you as to the character of the soil found in driving the test wells indicates that a layer of gravel from 18 to 24 feet in thickness was found in all of the wells, at a considerable depth beneath the surface, from which water could be pumped with freedom by a hand pump. These conditions are favorable to obtaining water freely from the ground here by means of wells. On the other hand, the extent of the meadow is limited, and the land surrounding it contains a large amount of ledge. With these conditions, and in the absence of a suitable pumping test from

wells in the meadow, it is not practicable to advise you definitely with regard to the quantity of water to be obtained from this source.

In view of the poor quality of the water now drawn from the wells in the valley of Stacy's Brook, and the need of an additional water supply, the Board regards the proposed locality as a suitable place in which to seek an additional supply of water. The Board would advise, however, that, before building all of the works for taking a supply from this source, you put in the necessary wells and connect them to a temporary pump, and test them by pumping continuously for a period of at least two weeks. during dry weather, in order to obtain more definite information as to the probable yield of the wells than is possible at present. It would also be well to have samples of the water collected at various times during the test, to determine what change, if any, takes place in its quality.

The Board will assist you by making such further analyses of water as may be necessary, and will give you further advice with reference to this matter, if you desire, when you have additional information to present.

Another application was received from this company, Oct. 24, 1896, after trials had been made relative to the capacity of the proposed wells for supplying water. The Board replied to this application as follows:—

Boston, Nov. 5, 1896.

The State Board of Health received from you, on October 24, a second application with reference to a proposed water supply to be taken from the ground in Thompson's Meadow, in which you state that additional wells have been driven in this locality, and a pumping test made by pumping from the wells for a period of twelve days continuously, except for short intermissions, aggregating in all about one and a half hours, at a rate of nearly 200,000 gallons per day.

Samples of water collected and sent in by you during this test have been analyzed by the Board, with the result that the quality of the water shows no material change from the quality of samples taken from test wells in August, and in its present state is excellent for the purposes of a public water supply.

With regard to the quantity of water to be derived from wells in this locality, the tests thus far made are not conclusive; but, considering the character of the land about the meadow and of the meadow itself, it seems to be very doubtful whether this source can be depended upon to furnish enough water for the needs of Swampscott and Nahant at all times. Taking into account, however, the favorable results of the tests thus far made as to the quality of the water, the comparative economy of this source on

account of its nearness to the present distributing system, as compared with any other source from which it is at all probable that a satisfactory supply can be obtained, and the desirability of avoiding, so far as possible, the use of water from your present wells in the vicinity of Stacy's Brook, the Board is of the opinion that this source is a proper one from which to take water for Swampscott and Nahant, at the present time.

In locating works for collecting ground water, it is desirable that they be extended through the meadow sufficiently to secure as great a quantity of water as possible from the ground. If, upon actual trial, it shall be found that the yield of this source is likely to be too small for the towns of Swampscott and Nahant at all times, it is very desirable that you continue your investigations, with the object of securing a permanent supply of water of good quality and in sufficient quantity to make it possible to discontinue the use of water from your present wells, which are not satisfactory for a domestic water supply, being located in territory containing a large and rapidly growing population, and a portion of them being apparently affected to a considerable degree by the presence of sea water.

UXBRIDGE. The selectmen and board of health of Uxbridge, acting conjointly, applied to the State Board of Health, April 28, 1896, for its advice relative to the quality of the water of a well in that town, proposed as an auxiliary source of public water supply for the town. The Board replied to this application as follows:—

Boston, July 3, 1896.

The State Board of Health has carefully considered your application of April 28, 1896, for advice with reference to the quality of the water of a well in the Capron mill yard, which it is understood you propose to use as an auxiliary source of water supply for Uxbridge.

The Board has caused an analysis of a sample of water from this well to be made, recently, and, taking the results of this analysis in connection with the results of analyses made in previous years, it is found that the water varies greatly in character from time to time.

Under the most favorable conditions, when little or no water has been drawn from the well for a long time, the quality of the water is not objectionable for the purposes of a public water supply.

All the analyses show that the water had previously been polluted and subsequently purified in a large degree in its passage through the ground to the well, but some of the analyses show the presence of a very large amount of free ammonia in the water, indicating that at such times the water entering the well is not thoroughly purified.

There is reason to expect, therefore, that, if water is pumped from this

source in such quantity as would probably be necessary for the supply of the town, imperfectly purified water from the sewage-polluted sources in the vicinity may enter the wells, and under the circumstances the Board does not consider this well a safe source of domestic water supply.

Ware. The water commissioners of Ware applied to the Board, May 27, 1896, for its advice relative to the quality of the public water supply, in consequence of the appearance at times of a considerable amount of organic matter in the water. The Board replied to this application as follows:—

Boston, July 3, 1896.

The State Board of Health has considered your application for advice with reference to the quality of the water of your present water supply, and has caused an examination of your works to be made, and samples of the water to be analyzed.

The analyses show that the water as it comes from the ground is colorless and free from taste and odor, and contains only an insignificant amount of organic matter. The water of your distributing reservoir, on the other hand, contains at times a large amount of organic matter, and microscopical analyses show that it contains large numbers of organisms which impart to the water a disagreeable taste and odor. Complaints as to the character of the water supplied to consumers are doubtless due to the deterioration of the water stored in your distributing reservoir, and the annoyance caused by the presence of minute organisms in this water. The sample of material collected from a faucet and sent in by you was probably composed of some of the larger organisms which are developed in the distributing reservoir.

The remedy for the trouble with the water is to keep it from exposure to light from the time it is drawn from the ground until it is delivered to the consumers. To accomplish this, it will be necessary to cover the present distributing reservoir or build a new covered reservoir or tank.

There is no reason to think that, if the quality of the water of your present sources remains as good as at present, it will support any growth that will cause the water to deteriorate if kept entirely from exposure to light.

Wellesley. The water supply committee of Wellesley applied to the Board, May 15, 1896, for advice relative to certain plans proposed by the committee for increasing its water supply and protecting the present sources from pollution. The Board replied as follows:—

Boston, June 4, 1896.

The State Board of Health received from you on May 15 an application for advice with reference to increasing the water supply of the town and protecting the purity of the present supply. You request, in particular, advice with reference to the following matters:—

- 1. The curtailment of waste.
- 2. The construction of a number of low dams to hold back the water of Rosemary Brook, with the hope of increasing the yield of the present sources by filtration from the brook into the well and filter gallery.
- 3. The taking of water directly from Rosemary Brook as an additional supply.
- 4. The construction of a filter gallery or system of tubular wells in the valley of Rosemary Brook, west of Cedar Street and north of Worcester Street, above your present works.
- 5. The necessity of preventing the pollution of Rosemary Brook and its tributaries.
- 6. The removal of a small factory and buildings south of the driveway from Cedar Street to the pumping station.
- 7. The purchase of land south of the pumping station.

In connection with the question of constructing a filter gallery or system of tubular wells in the valley of Rosemary Brook, above your present works, you submit a plan showing the location of test wells, and samples of the soil from these wells collected in 1892.

With reference to the first question,—the curtailment of waste,—the Board is informed that, notwithstanding the fact that water is generally supplied through meters to consumers in the town, only about fifty per cent. of the water pumped is accounted for. The consumption of water per inhabitant in Wellesley in 1895 amounted to 42 gallons, which is not excessive, as compared with the consumption in other towns similarly situated. If, however, the consumption of water, as shown by your pumping records, could be reduced one-half, there would be a saving in the cost of pumping, and the necessity for an additional supply might not appear for a time. It is, therefore, desirable that an investigation be made, to determine whether a large quantity of water is lost by leakage or otherwise, and whether this loss can be prevented.

Judging from your experience last year, when dams were constructed upon Rosemary Brook, in the vicinity of your present sources, it appears that a considerable increase in the quantity of water entering the well and filter gallery was obtained by the construction of these dams. It is probable also that in previous years, before the construction of these dams, a

portion of the water entering your present sources was derived by filtration from the brook. Analyses of samples of the water of the well and filter gallery have been made from time to time by the State Board of Health, and its quality has apparently always been satisfactory. The well and filter gallery, however, are both situated close to the brook, and the chief danger from increasing the quantity filtering from the brook is that some of the water may pass too directly through the ground into the filter gallery or well, and not become satisfactorily purified in its passage. In some cases water taken from sources situated as yours are has continued to be satisfactory for many years, while in others, after a longer or shorter period of use, the quality of the water has deteriorated, owing to the imperfect filtration of the water from the stream or pond near by. Increasing the height of the water in Rosemary Brook by means of dams will tend to cause the water to filter more rapidly through the ground, thereby producing conditions more favorable to imperfect filtration.

With reference to the use of water taken directly from Rosemary Brook for the supply of the town, and the necessity of preventing the pollution of Rosemary Brook and its tributaries, the Board has caused an examination of this brook to be made by one of its engineers, and finds that it is exposed to direct sewage pollution from factories and dwelling-houses on its banks, and to pollution from farms and cultivated lands upon its watershed, and is, therefore, a dangerous source from which to take water directly for domestic purposes, and such water should not be distributed to your people. The watershed of the brook drains a part of the villages of Needham and Highlandville, and the population upon it is likely to increase rapidly in the future, so that it would not be possible, without excessive care, to prevent the pollution of the stream. Nevertheless, in view of the nearness of your present well and filter gallery to the brook, it is desirable that it be kept free from pollution, as far as is practicable.

An examination of the results obtained from test wells driven in the valley of Rosemary Brook, west of Cedar Street, and north of Worcester Street, in 1892, does not indicate that the conditions are favorable to obtaining a large amount of water from the ground there. South of Worcester Street the results of investigations were more favorable, judging from the samples of material submitted. The tests appear to have been confined to the vicinity of the north-westerly shore of Longfellow's Pond, and it is possible that better conditions could be found near the upper end of the pond and in the valley of the brook above, where the character of the surface indicates that the soil may be more porous.

The information available to the Board is not sufficient to enable it to advise you definitely at present with reference to the best method of increasing the water supply of Wellesley. The town is growing rapidly, and

in the selection of an additional water supply provision should be made for a large increase in the consumption of water in the future. The examinations thus far made in the valley of Rosemary Brook, above your present sources of supply, by means of test wells, have been unfavorable to obtaining a large increase in your present supply here; but, as already stated, the conditions appear, from surface indications, to be somewhat more favorable farther up the valley, and it is possible that a large addition to your present supply can be obtained in this region.

It is to be considered, however, that the population in the valley of Rose-mary Brook is already large, and may increase rapidly in the future, owing to its nearness to the metropolitan district; and, before deciding upon a plan for increasing the water supply of Wellesley by the construction of further works in this valley, the question of the feasibility of obtaining a supply of water for domestic purposes here that can be maintained in a satisfactory condition for a reasonable time in the future, without excessive cost, should be carefully considered. It is also very important, before deciding definitely as to a source of additional water supply, that you determine the feasibility and probable cost of obtaining a supply from, or in connection with, the metropolitan district.

The presence of a small factory and other buildings between Cedar Street and the wells south of the driveway from Cedar Street to the pumping station does not appear to be, under present conditions, a serious menace to the quality of your water; and the removal of these buildings is not essential, if means are taken to prevent sewage from polluting the stream or from getting into the ground, and so passing to the filter gallery or well.

With reference to the advisability of purchasing any of the land lying east of Cedar Street, south of the pumping station, it may be said that, if water from this territory finds its way into your present sources of supply, it is desirable that the land be owned and controlled by the town. It is not feasible to determine how much of this land it is desirable for the town to control, except by experiment.

In conclusion, the Board would advise that you have the whole subject of your present and future water supply thoroughly examined by a competent engineer, to determine what measures are necessary to protect the purity of your present sources of supply, and the most appropriate source from which to take an additional supply.

The Board will, upon application, advise you further in this matter when you have the results of further investigations to present.

WILLIAMSBURG. The selectmen of Williamsburg applied to the Board, Feb. 11, 1896, for its advice relative to a water supply for

the town to be taken from the East Branch of Mill River. The Board replied to this application as follows:—

Вовтом, Ост. 1, 1896.

The State Board of Health has carefully considered your application with reference to a proposed water supply for Williamsburg, to be taken from the East Branch of the Mill River, upon which it is proposed to construct a small reservoir above the village, and has caused an examination of the proposed source to be made by one of its engineers, and samples of the water to be analyzed.

About three-fourths of a mile up stream from the place where it is proposed to locate the reservoir the East Branch is joined by Bradford Brook, and at the point of junction the two streams have nearly equal watersheds. These streams will furnish by far the greater portion of the water which will enter the proposed reservoir, and samples from each of them, collected at different seasons of the year, have been analyzed with a view to comparing the quality of the water.

The water of the East Branch above the Bradford Brook is soft, has very little color, and contains a small amount of organic matter for a surface water. The water of Bradford Brook, on the other hand, is harder, and has at times considerable color, and contains a greater amount of organic matter. The quality of the water of the proposed reservoir would be somewhat better than the Bradford Brook water, but not so good as the water of the East Branch, above Bradford Brook.

The watershed above the proposed reservoir contains a considerable number of farmhouses, though the population per square mile is small. Several of the buildings are located near the streams, particularly in the Bradford Brook watershed, and provision will have to be made to prevent sewage from these houses entering the streams and polluting the water supplied to the town. In the watershed of the East Branch, above Bradford Brook, the houses are more remote from the stream than in the Bradford Brook watershed, and the population per square mile is considerably smaller.

Considering all the circumstances, therefore, a more satisfactory supply for the town could be obtained by taking water from the East Branch, above the Bradford Brook, than at the point proposed.

With regard to the quantity of water that would be furnished by the East Branch, below Bradford Brook, it may be said that the indications are that the quantity would be ample at all times for the supply of Williamsburg. It is also probable that an ample supply would be obtained by taking water from the East Branch, above the Bradford Brook; and, in case an additional supply should be needed at any time, provision might be

made for drawing water from Bradford Brook in emergencies. The cost of taking a supply from the East Branch, above the junction of Bradford Brook, would probably be somewhat greater than at the place proposed in the application; but, in view of the better quality of the water, and the less number of dwellings and their distance from the stream, the Board would advise the town to take its supply from the East Branch, above Bradford Brook, rather than at the point proposed.

Woburn. The water commissioners of Woburn applied to the Board, April 30, 1896, for its advice in regard to the existence of a disagreeable taste and odor in the public water supply. The Board replied to the application as follows:—

Boston, June 6, 1896.

The State Board of Health has considered your application for advice with reference to a disagreeable taste and odor in the water supply of the city, and has caused an examination of your distributing reservoir to be made, both when the reservoir was full and after the water had been completely drawn off.

Frequent chemical analyses of the water of your filter gallery for several years have shown that the water is colorless and free from taste and odor, and contains very little organic matter, while microscopical examinations show that the water is practically free from vegetable or animal organisms. Examinations of the water of the distributing reservoir, on the other hand, have shown that the water contains at times a large amount of organic matter, and often large numbers of vegetable organisms which impart to the water a disagreeable taste and odor.

These organisms may grow as abundantly and affect the quality of the water as seriously in the colder months of the year as in the warmer months. There is no doubt that the disagreeable taste and odor complained of in the water supply of the city of Woburn is due to the presence of these organisms in the distributing reservoir.

It has been well known for many years that a ground water deteriorates on exposure to light in an open reservoir, such as that in use at Woburn, and experience has clearly shown that the remedy for this trouble is to keep the water from exposure to light from the time it comes from the ground until it reaches the consumer. To accomplish this in the case of the Woburn water works, it will be necessary either to cover the present distributing reservoir or to build a new covered reservoir or tank, which may be of comparatively small capacity and sufficient only for ordinary purposes, if the present reservoir is kept for use in emergencies.

There is no reason to think that, if the quality of the water of your

present filter gallery remains as good as at present, it will support any growth that will cause it to deteriorate, if kept entirely from exposure to light.

SEWERAGE AND SEWAGE DISPOSAL.

The following is the substance of the action of the Board during 1896, in reply to applications for advice relative to sewerage and sewage disposal:—

Agawam. The selectmen of Agawam applied to the Board, June 10, 1896, for its advice relative to the disposal of sewage from a proposed sewer for the village of Mittineague, into the Westfield River. The Board replied to this application as follows:—

Boston, July 3, 1896.

The State Board of Health received from you, on June 8, an application for advice with reference to the disposal of the sewage of a portion of the village of Mittineague, situated in the northerly part of Agawam, by discharging it without treatment into the Westfield River. The application was accompanied by a plan showing three possible outlets of the proposed sewer, two of which are into the tail-race leading from the Worthy Paper Company, and a third into the Westfield River, about 100 feet below the outlet of the tail-race.

The Board has carefully considered your application, and has caused an examination of the locality to be made by one of its engineers, and concludes that the disposal of the sewage of this village by discharging it untreated into the Westfield River is permissible for the present.

The sewage should not be discharged into the tail-race, because at times when the mill is not running there is no flow of water in the tail-race, and the discharge of sewage into it would, under these conditions, cause a nuisance.

In discharging the sewage into the river, the Board advises that the outlet of the sewer be carried well out into the stream, so that floating matters from the sewage may not lodge on the shore in the vicinity of the outlet.

Attleborough. A communication was received from the Board of Health of Attleborough, Aug. 29, 1896, stating that they had received a petition from citizens of Attleborough, remonstrating against the discharge of sewage from that town into Ten Mile River, at the same time requesting the Board "to examine the

locality, and offer suggestions as to a remedy." The Board replied to this letter as follows:—

Boston, Oct. 1, 1896.

The Board has caused an examination of the locality to be made by one of its engineers, and finds that the sewer in question discharges into the river just below the bridge at County Street, and that there is another sewer from Attleborough, discharging into the river about 4,000 feet further down stream. The lower sewer outlet is located just above the Dodgeville mill pond, which is said to give off very offensive odors at times. There are several other mill ponds upon the stream below.

From information furnished by you, it is learned that these sewers were originally constructed for surface drainage only, and you estimate that the sewage from about 3,500 people is now disposed of by discharging it directly into the river through these sewers. The Board is also informed that large quantities of ice are harvested from the mill pond below the sewer outlets, and that the river is used as a direct source of water supply by the town of East Providence, in Rhode Island, situated a little less than ten miles below Attleborough.

The discharge of sewage from 3,500 people into a stream of the size of the Ten Mile River would inevitably produce a nuisance, and the condition of the mill pond below the sewer outlets will grow rapidly worse, owing to the decomposition of organic matter deposited from the sewage upon the bottom and sides of the pond. Extending the sewers to a point of discharge further down the stream would simply transfer the nuisance to another locality. The only way by which the nuisance can be avoided is by discontinuing the discharge of unpurified sewage into the river. The disposal of sewage by the present method is not only a nuisance to the inhabitants of Attleborough, but is contrary to existing laws, and is a source of great danger to those using ice and water from the river below Attleborough.

Under the circumstances, the Board considers it very important that a proper method of sewage disposal be adopted, and put in practice without delay. The Board is prepared to assist you in this matter, if you desire, by advising you with reference to any plans that you may wish to submit to it providing for the disposal of the sewage of Attleborough.

Brockton. The mayor of Brockton applied to the Board, Sept. 22, 1896, for its advice relative to plans for the drainage of two small districts in Brockton. The Board replied to this application as follows:—

BOSTON, Sept. 24, 1896.

The State Board of Health has carefully considered the plans presented by you for the approval of this Board, under the provisions of chapter 309 of the Acts of 1889, providing for the drainage of two small districts in the city of Brockton, — one known as the Weston Street district and the other as the Battles Street district, — and hereby approves the plans for the said drainage systems.

BROCKTON. The city engineer of Brockton applied to the Board, Sept. 14, 1896, requesting the opinion of the Board relative to the propriety of fertilizing the growing crops upon its sewage disposal areas "with frequent doses of sewage." To this application the Board replied as follows:—

Boston, Oct. 2, 1896.

In reply to your letter of September 14, asking the opinion of this Board as to the propriety of using the growing crops on your sewage fields as food for human beings, the Board instructs me to say that in its opinion no harm can arise from the use of such vegetables as are cooked before being used, and such grain and other products used for food which cannot come in actual contact with sewage.

Danvers. The board of health of Danvers applied to the State Board, Feb. 7, 1896, for its advice relative to the disposal of the sewage of certain morocco shops in that town. The Board replied to this application as follows:—

Boston, July 22, 1896.

The State Board of Health received from you on Feb. 7, 1896, an application for advice with reference to the disposal of the manufacturing sewage from the morocco shops or tanneries in Danvers which is now discharged into Crane's River, in which you state that you have under consideration a plan providing for the discharge of the sewage into two large settling tanks, through which you propose to cause the sewage to flow slowly, thereby allowing the heavier matters to settle, and to discharge the effluent into the stream; and you request advice as to whether, by this method, if the tanks are frequently cleaned ont, the difficulty of the present system of disposal would not be largely overcome.

Since the application was received the Board has been investigating the character of this sewage, and conducting experiments with a view to suggesting a practicable method of disposing of it in such a manner as to prevent further objectionable pollution of the stream and mill pond. While these investigations have not yet been carried far enough to enable the Board to advise you definitely as to a method of finally disposing of sewage

of this character, the results thus far obtained indicate that it will probably be feasible to dispose of it by some method of filtration after the greater portion of the suspended matter has been removed. It has been found, in the course of the investigations, that much of the suspended matter in the sewage settles out readily upon allowing it to remain practically undisturbed, and experiments at the factory indicate that somewhat more than half of the putrescible organic matter can be removed from the sewage by allowing it to stand for a period of about two hours.

In view of the desirability of keeping as much organic matter as possible out of the stream, and of the probable necessity for the use of settling tanks in connection with any method of disposal that is likely to be adopted, the Board advises, as the first step in overcoming the objectionable condition, that you construct settling tanks of sufficient capacity to allow the sewage to settle for a period of two hours, if it shall be found upon examination that the tanks can be operated satisfactorily by gravity.

Investigations as to the quantity of sewage discharged from the tanneries and the rate of flow indicate that the rate is quite regular, and that the quantity averages about 20,000 gallons per hour during working hours. In order to allow this quantity of sewage to settle for a period of approximately two hours, settling tanks having a larger capacity than those proposed by you will be necessary.

In order to obtain the full benefit that may be derived from the use of settling tanks, it is essential that all of the sewage now discharged into the brook be collected and conveyed to the tanks, and that the tanks be cleaned out frequently. Once in two days may be often enough, though it may become necessary to clean them out daily, so that their capacity may not be greatly reduced, and the length of time allowed for sedimentation materially shortened by allowing the sediment to accumulate to a considerable depth in their bottoms. The tanks, therefore, should be so located and arranged that the supernatant liquid may be drawn off when necessary, and the sludge readily removed at frequent intervals. The tanks should also be designed with a view to the possible necessity of pumping the supernatant liquid to a place of disposal, if this should subsequently be found necessary.

With properly designed tanks, operated with care, a very large portion of the suspended matters which constitute much of the total putrescible organic matters in the sewage can be prevented from entering the pond.

The quantity of sludge to be removed will be large, but not so great that it cannot be removed in carts without special difficulty. The so-called odorless carts may be best adapted to the purpose. The sludge can be disposed of upon filter beds not far from the factory, where areas well suited to the purpose can be found.

The Board would advise that the work of designing the tanks and of preparing the areas for the disposal of the sludge be committed to an engineer of experience in matters relating to sewage disposal.

An examination of the condition of the mill pond and the character of the nuisance caused by it shows that the bottom and sides of the pond, especially near its upper end, are covered with organic matter from the sewage, and at times when these areas are uncovered the odor from them is very offensive. When the pond is full and these areas are covered with water, it appears that the nuisance is much less serious.

In view of this condition, and of the probability that, even if the discharge of sewage into the pond should be wholly prevented at once, there would still, for a considerable time, be a serious odor from these areas when exposed, the Board would suggest that you consider the feasibility of obtaining control of the mill privilege at the outlet of the pond, and of keeping the pond full at all times.

The Board will again communicate with you with regard to this matter when the results of further investigations now being made are available.

Danvers Lunatic Hospital. The trustees of the Danvers Lunatic Hospital applied to the Board for its advice, Sept. 27, 1895, relative to a plan for disposing of the sewage of the hospital by precipitation with chemicals, followed by filtration through a small area of coke. This application was withdrawn, Oct. 28, 1895, and afterward resubmitted, with modified plans. The Board replied to this application as follows:—

Boston, May 7, 1896.

The State Board of Health has considered your application with reference to a proposed system of purification for the sewage of the Danvers Lunatic Hospital, the essential features of which are a precipitating tank, in which it is proposed to precipitate the solid matters of the sewage by the application of chemicals, and a filter bed composed of coke, having an area of about a quarter of an acre and a depth of three feet, through which it is proposed to filter the sewage after it passes through the precipitating tanks.

The quantity of water used for the supply of the hospital is from 100,000 to 125,000 gallons per day, and, assuming that this represents approximately the amount of sewage to be disposed of, the rate of filtration through the coke filter would be about 500,000 gallons per acre per day. The sewage from the hospital appears to be quite dilute, judging from the results of an analysis made by the Board, and if the usual percentage of organic matter should be removed by chemical precipitation, it is possible that for a time, with great care in the management of the filter,

a large percentage of the remaining organic matter would be removed from the sewage by the proposed filter; but it is probable that, in order to purify the sewage satisfactorily, the size of the filter would have to be considerably enlarged.

The disposal of the sewage of the hospital by this plan would involve a very great expense both for construction and maintenance, as compared with the disposal of the sewage on land if an area suitable for the purpose can be found within a reasonable distance of the hospital.

With a view to learning whether there is any such land in the vicinity of the hospital, the Board has caused a general examination of this territory to be made by one of its engineers, and finds that there is a considerable area of sandy land, situated on the south-westerly side of West Street, between the street and the Ipswich River, a little over half a mile from the hospital buildings, portions of which appear to be well adapted for the purification of sewage by intermittent filtration; moreover, the situation of this area is such that sewage can probably be conveyed to it by gravity at a small expense from your present sewage carriers, which are at present laid to within about 1,000 feet of this area.

In view of all the circumstances, the Board would advise that you have an investigation made, to determine the feasibility of disposing of the sewage of the institution upon this area by intermittent filtration; and the Board will, upon application, advise you further with regard to this matter when you have the results of further investigations to present.

METROPOLITAN SEWERAGE COMMISSION. An application was received from the Metropolitan Sewerage Commission, Oct. 9, 1895, under the provisions of chapter 406 of the Acts of 1895, for the approval of the Board of a system of sewage disposal for a district lying partly in the city of Boston and the towns of Milton, Hyde Park and Dedham, in the valley of the Neponset River, and for a portion of Newton and the town of Brookline lying in the valley of the Charles River. The Board replied to this application as follows: -

Возтом, Feb. 18, 1896.

The State Board of Health has considered your application with reference to a proposed system of sewage disposal for that portion of the city of Boston and the towns of Milton, Hyde Park and Dedham lying within the valley of the Neponset River, and portions of the city of Newton and the town of Brookline lying within the valley of the Charles River. application is accompanied by a plan and profiles and a report of your engineer, giving details of the proposed scheme approved and adopted by your Board, in accordance with a provision of chapter 406 of the Acts of 1895.

The plan provides for a main sewer from a point on Worley Street, near Weld Street, in the West Roxbury district of the city of Boston, through various streets and private lands to the bank of the Charles River, a short distance above the Brookline water works pumping station; thence in the vicinity of the right bank of the Charles River and along the left bank of Mother Brook and the Neponset River to the Dorchester intercepting sewer of the city of Boston at Central Avenue in Dorchester. The capacity of the latter sewer is limited by a section below Baker's Court in Dorchester, which has a capacity of only about 20 cubic feet per second; and it is estimated that the capacity of this sewer, if the sewage of the Neponset valley is discharged into it, will be attained about the year 1905. To provide for the disposal of the sewage after this date two methods are suggested, by either of which the sewage in the Neponset intercepting sewer would be diverted at a point on River Street, Hyde Park, about 500 feet below the Mattapan paper mill, and conveyed by gravity either to the Boston main drainage sewer at Squantum or an independent outlet at Nut Island in Quincy. With this end in view, the Neponset intercepting sewer has been designed with a capacity above the point of diversion estimated to be sufficient for the probable needs of the valley until 1930, while below this point the capacity is proportioned to that of the limiting section of the Dorchester intercepting sewer, estimated to be sufficient until 1905.

In designing the Boston main drainage system it was anticipated that the sewage from the higher portions of the district bounded by the Charles River, Mother Brook and the Neponset River could be at some future time intercepted by a "high-level" sewer and conveyed to Squantum by gravity, thus affording relief to the pumping station and tunnel when the flow of sewage shall tax their capacity; and provision was made, in the construction of the works, for the connection of such a sewer with the outfall works at Squantum and Moon Island. Your investigations indicate that a feasible route for this sewer can be found, which would intercept the proposed Neponset valley sewer at the point where its size is reduced, on River Street in Hyde Park. Your investigations also indicate that a feasible route for an intercepting sewer from this point to Nut Island may also be found. With regard to disposing of the sewage in the future by either of these methods the Board can express no opinion, with the information available at the present time, and you have verbally requested that the consideration of these matters be omitted. The Board has accordingly considered only that portion of your application which refers to the disposal of the sewage of the Neponset valley by means of the proposed sewer shown on the plan contained in the seventh annual report of your Board, opposite page 38, which provides for the discharge of the sewage into the Dorchester intercepting sewer at Central Avenue in Dorchester.

With regard to this portion of the scheme, the Board finds that the proposed sewer will provide a satisfactory means of disposal for the sewage of the territory in the Charles and Neponset valleys which it is estimated to serve, probably until about the year 1905, if care is taken in the construction of the main sewer and tributary systems to exclude surface and ground water from the sewers so far as possible, and if the amount of manufacturing sewage is restricted by preventing the discharge into the sewer of water from manufacturing establishments that can be properly discharged into natural water courses.

The size of the proposed sewer above the point where it is expected that the sewage will be diverted at some future time appears to be sufficient to make a reasonable provision for a population as great as may be expected to be connected with this portion of the system in 1930, so far as can be judged by present indications. The size of the sewer below the point where it is expected that the sewage of the Neponset intercepter may be diverted is such as to serve the low districts in Dorchester and Milton for many years after the sewage of the upper portion of the system is diverted.

The Board approves the plan of disposing of the sewage of the Neponset valley by discharging it into the Dorchester intercepting sewer of the city of Boston, but expresses no opinion as to the most appropriate method of disposal to adopt after the capacity of this sewer is reached. The increase in the amount of sewage to be disposed of by the Boston main drainage system will necessitate before long the enlargement of the reservoir capacity at Moon Island, and the necessity for enlargement will be hastened by the addition of the Neponset valley sewage.

It is understood that the sewerage systems to be connected with the Neponset valley sewer shall be constructed upon the so-called "separate" plan, and that no sewage overflows will be used in connection with the main sewer or tributary systems.

On March 18, 1896, the Metropolitan Sewerage Commission again wrote to the Board, as follows: -

110 BOYLSTON STREET, BOSTON, March 18, 1896.

Gentlemen: - In your reply of Feb. 18, 1896, to our application for approval of plans for sewage disposal for Neponset River valley, at the close you say: "It is understood that the sewerage system to be connected with the Neponset valley sewer shall be constructed upon the so-called 'separate' plan, and that no sewage overflows will be used in connection with the main sewer or tributary systems." As we are

informed and understand, you do not, by the use of the words "no sewage overflows will be used," etc., intend to prohibit or prevent the construction of such provision for temporary overflows as it would seem necessary should be provided for use in case of accident or necessity of repair of trunk sewer. Unless we hear from you to the contrary, we shall proceed to construct the main trunk sewer and approve local connections therewith, making and requiring such provision for such overflows similar to those provided and required in the Charles River and north metropolitan systems, to be used only in case of emergency.

Very respectfully yours,

For the Board,

(Signed) Edward P. Fisk, Clerk.

The Board of Health replied to this letter as follows: —

Boston, March 26, 1896.

The State Board of Health received from you, on March 18, a communication with reference to the use of sewage overflows in connection with the proposed Neponset valley sewerage system, in which you state that unless you hear from the Board to the contrary you shall proceed to construct the main trunk sewer and approve local connections therewith, making and requiring such provisions for such overflows similar to those provided and required in the Charles River valley and north metropolitan systems, to be used only in case of emergency.

The plan presented by you for an intercepting sewer for Neponset River and Mother Brook basins, including a portion of the Charles River basin, which this Board approved in its communication dated Feb. 18, 1896, did not contain any provision for sewage overflows, and no mention of sewage overflows was made in the report of your engineer submitted with the application.

Before the Board can approve a plan providing for sewage overflows, it will be necessary that you submit a plan showing the location of the proposed overflows, with a description of the proposed method of constructing and operating them.

The Sewerage Commission again wrote to the Board, April 18, 1896, as follows:—

110 BOYLSTON STREET, BOSTON, April 18, 1896.

GENTLEMEN: — In response to your communication of March 26, 1896, stating that a plan will be required showing the proposed overflows from the Neponset valley intercepting sewer, with a description of method of

construction and operation, the Board desires to state as follows: The Charles River system has been operated since 1892 as a branch of the Boston main drainage. During the rainy weather, and when the pumps are not in operation, the trunk sewer of the Boston system has been surcharged, flooding the Charles River branch, and requiring the construction and maintenance of automatic overflows for the efficient and safe operation of the system. The Board has deemed it expedient to require, for safety and convenience in maintaining and repairing the sewer, and as a further safeguard against flooding from Boston's system that cities and towns tributary to the Charles River system should also construct and maintain automatic overflows at all their connections from areas of considerable size.

The Neponset valley intercepter, like the Charles River main, will, when completed, be operated as a branch of the Boston system; and it is anticipated that it also will be subject, at its lower end, to flooding during the surcharged condition of the Boston trunk sewer. The Board is of the opinion that the safe operation of the Neponset branch will require the following overflows from the main sewer:—

First. — At Granite bridge, Dorchester, an automatic overflow into the tidal currents of Neponset River, having a carrying capacity equal to the main sewer at that point.

Second. — Near Mill Lane, Dedham, an overflow into Mother Brook, having a carrying capacity equal to the main sewer at that point, controlled by a Penstock valve, to be operated by hand, and only when the main sewer is surcharged at that point.

Plans of the proposed overflows are submitted, as requested.

For convenience and safety in maintenance, to provide against possible accident or injury to the main sewer or flooding at low levels from Boston main sewer, the Board is of the opinion that, as in the Charles River branch, automatic safety overflows should be provided from all local connections receiving drainage from ten acres or more; such overflows, above East Street, Dedham, to be permanently sealed off, and never used so long as the Charles River and its shores are used as a source of domestic water supply.

At the date of the engineer's preliminary report on the Neponset valley sewer the Board had not decided to acquire the Dorchester intercepter from Central Avenue to Granite bridge, and were not prepared and did not at that date ask advice in the matter of overflows from the main sewer. With the exception of Milton, no city or town of the valley above Central Avenue had then prepared any studied scheme for its local connections, and the Board were equally unprepared to ask advice at that date in the

matter of overflows from local connections. The engineer to the Board, after conference with the engineers for the tributary cities and towns, has prepared a study for a system of branches for local connections, which are shown on the accompanying map, subject to such minor modifications of size, location, etc., as may necessarily be developed during the more detailed surveys for the construction of local sewers. The Board desire to approve and adopt automatic relief overflows at all the connections shown, with the understanding that such as are above East Street, Dedham, shall not be opened for use so long as the Charles River is used as a source of water supply for Brookline, Newton and other cities. A characteristic study for one of these connections is submitted, and your advice and approval is asked in the matter of overflows from the main sewer and from local connections as outlined above.

Respectfully submitted,

For the Board,

(Signed) EDWARD P. FISK, Clerk.

The Board of Health replied to this application as follows: -

Boston, May 7, 1896.

The State Board of Health received from you, on April 18, an application for approval of proposed sewage overflows in connection with the proposed Neponset valley intercepting sewer, accompanied by plans showing the location of proposed overflows from the main sewer and tributary systems and designs for these overflows. Two of these overflows are proposed for the discharge of sewage from the main intercepting sewer, and it is understood that the others are automatic overflows, to be connected with the tributary systems near their junction with the main sewer, by which sewage from the tributary sewers may be discharged into local water courses when the sewage in the intercepting sewer rises to a certain height. One of the proposed overflows presented by you is located upon the main sewer at Granite bridge, but, since this is below the portion of the sewer to which the reply of the Board dated February 18 was limited, at your request, the Board has omitted the consideration of this overflow.

It is stated in the application that your Board "desire to approve and adopt automatic relief overflows at all connections shown, with the understanding that such as are above East Street, Dedham, shall not be opened for use so long as the Charles River is used as a source of water supply for Brookline, Newton and other cities." As the discharge of sewage into the Charles River in this vicinity is, under present conditions, prohibited by law, this Board cannot approve any overflows upon this portion of the sewer at the present time. The overflows under consideration, therefore,

are those included on the main sewer and tributary systems, between the point where the sewer crosses East Street in Dedham and its junction with the Dorchester intercepting sewer at Central Avenue, Dorchester.

By the existing conditions, sewage from all overflows in this district would naturally be discharged either into Mother Brook or the Neponset River, or tributaries of these streams. There are several dams along Mother Brook and the Neponset River, forming mill ponds in some cases of considerable size, and all of the proposed overflows would be above one or more of these dams. There is a large and rapidly growing population in the vicinity of these streams and their tributaries, and, in the opinion of the Board, it is desirable that these streams be kept free from pollution, and that the discharge of sewage into them be prevented, if possible.

Regarding the danger of the proposed main sewer and tributary systems becoming surcharged by sewage backing up from the Boston system, the Board is informed that by existing provisions the Dorchester intercepting sewer is automatically disconnected from the Boston main drainage sewer at times when the latter is surcharged, and provision is made whereby the Dorchester intercepting sewer may at such times discharge into tide water; moreover, according to the plan approved by this Board in a communication to your Board, dated Feb. 18, 1896, the bottom of the Neponset valley sewer at its lower end in Central Avenue, Dorchester, is at about grade 20, or several feet above high water. It does not seem to this Board that there is danger that the Neponset valley sewer may be surcharged from this cause.

Regarding the necessity of automatic overflows for safety and convenience in maintaining and operating a separate system of sewers, much information is furnished by experience in the operation of such systems already in use in this State. A number of such systems have been in successful operation in some cases for several years without automatic overflows, and information regarding these systems indicates that the necessity for such overflows has not arisen.

In view of all the circumstances, the Board declines to modify its approval, under date of Feb. 18, 1896, of a system of sewage disposal for Neponset River valley which had been submitted by you, by adopting, as a part of that plan, the plan of automatic relief overflows proposed in your communication of April 18, 1896.

It is possible that there are points in the system not known to this Board where unusual emergencies may occur, and where safety would require an outlet gate which can be opened temporarily; if such points are found to exist, this Board will consider plans you may present in regard to them; but this Board is desirous to avoid discharging sewage above any of the mill dams on Neponset River, when not absolutely necessary.

Metropolitan Sewerage Commission (Dorchester intercepting sewer). The sewer commissioners applied to the State Board of Health, May 2, 1896, for the approval of the Board of the taking of a part of the Dorchester intercepting sewer to constitute a part of the sewerage system for a part of the city of Boston and for the towns of Dedham, Hyde Park and Milton. The Board replied to this application as follows:—

Boston, June 6, 1896.

The State Board of Health has considered the application submitted by you on May 4, 1896, in which you request the approval by this Board of the taking by the Metropolitan Sewerage Commissioners of the portion of the Dorchester intercepting sewer between Central Avenue and Granite Avenue, in Dorchester, as a portion of the proposed Neponset valley sewerage system, provided for by chapter 406 of the Acts of the year 1895, and, having carefully considered the plans, hereby approves them as a part of the system of sewage disposal for the Neponset valley, supplementary to the plans already approved by this Board.

NATICE. The sewerage committee of Natick applied to the State Board of Health, July 1, 1896, for its approval of a system of sewerage and sewage disposal being constructed for the town, under the provisions of chapter 459 of the Acts of 1894. The Board replied to this application as follows:—

Boston, Sept. 3, 1896.

The application was accompanied by plans showing a general system of sewerage for the thickly settled portion of the town, and a main sewer leading from the town through West Central Street to a pumping station located on the northerly side of the street, and between it and the Boston & Albany Railroad and close to the southerly end of Lake Cochituate. From the pumping station a force main extends across the railroad and private land to Speen Street, through this street to the Worcester turnpike, and westerly, along the turnpike, to a place of disposal upon land upon the opposite side of the street from land now used for a similar purpose by the town of Framingham.

The proposed filtration area indicated upon the plans contains an area of $97\frac{1}{2}$ acres of land, of which it appears that 74 acres can be utilized for sewage-disposal purposes. At the time the application was made the construction of the system had nearly been completed.

The Board, having carefully examined and considered the plans submitted, hereby approves the system of sewerage and sewage disposal, as indicated by these plans.

It will be unnecessary to prepare all of the filter beds indicated upon the plan at the present time, but at least eight of these beds should be completed early in 1897, to provide for the disposal of sewage that may be expected to reach the beds as soon as the sewers now constructed shall have come into general use, and additional beds may then be prepared from time to time as they are needed.

Springfield. The mayor of Springfield applied to the Board, April 21, 1896, for its advice relative to the construction of a sewer for a certain portion of the city, having its outlet into the Connecticut River at the foot of Elm Street. The Board replied to this application as follows:—

Boston, May 7, 1896.

The State Board of Health received from you, on April 21, 1896, an application with reference to the proposed extension of the Elm Street sewer to the bank of the Connecticut River, and the construction of a pipe to discharge the dry-weather flow of the sewage at a distance from the shore of the river. The Board finds that the proposed extension appears to be adapted to disposing of the dry-weather flow of sewage at such a distance from the shore that it is not likely to return until it becomes well diluted, and approves the disposal of the sewage from this sewer by the method proposed. As in the case of the plans submitted last year, the Board advises that it would be well to avoid the upturning of the discharge pipe at the end, and to provide a free outlet, with no depressed portion of the pipe in which solids from the sewage may be deposited.

STOCKBRIDGE. An application was received from the sewerage committee of Stockbridge, Nov. 27, 1896, for advice relative to a proposed system of sewerage and sewage disposal in that town. The Board replied to this application as follows:—

Boston, Jan. 8, 1897.

The State Board of Health received from you, on Nov. 27, 1896, an application for advice with reference to a proposed system of sewerage and sewage disposal for the village of Stockbridge, accompanied by a plan showing the territory which it is intended to include in the system at the present time, and a plan of a proposed filtration area near the Housatonic River, north-west of the village. Subsequently, plans were received showing the locations of the proposed sewers and the proposed method of preparing the filtration area.

The Board has examined the plans submitted and has caused an examination of the locality to be made by its engineer, and samples of the

soil, collected from test pits on the proposed filtration area, to be analyzed.

The plans show that it is feasible to collect the sewage from practically all of the village, and deliver it by gravity upon the filtration area. The exclusion of storm water from the sewers, as proposed, is very desirable, since smaller sewers will be required, and the quantity of sewage to be purified will be much less than if storm water should be admitted. The proposition to place underdrains beneath the sewers should also be carried out, for the same reason.

The area proposed for the disposal of the sewage appears to be the most suitable one which it is practicable to use for the purpose without pumping, and its location is satisfactory from a sanitary point of view. Examinations of the ground where the filter beds are to be located, by means of test pits, have shown that beneath a layer of loam and soil at the surface there is a layer of sand from 2 to 3 feet in thickness, which, if properly underdrained, is suitable for the purification of sewage by filtration. The depth of the material is less than is necessary for the proper filtration of the sewage, but it is feasible to increase the depth, as proposed in the plans submitted, to about four feet, by removing the soil from the present surface and replacing it with good filtering material from higher land in the vicinity, where suitable material is found. The depth of the filters will be somewhat less than is desirable, but the quality of the filtering material is such that a well-purified effluent can be obtained from the proposed beds with reasonable care in their management.

According to the plan, about 2.2 acres of filter beds can be prepared here, and a further area of a little over an acre situated near the river bank can be utilized by means of trenches, if necessary, though the quantity of sewage that can be disposed of in this way would be considerably less per acre than upon the filter beds. It is proposed to prepare in the beginning four of the filter beds shown upon the plan, aggregating about 1.5 acres in area, and this area should provide for the diposal of the sewage of the present village for several years after sewers are introduced.

On account of the comparatively small elevation of the filter beds above the level of the water in the river, their operation may be interfered with occasionally by freshets; but no serious trouble is to be anticipated from this cause if no change is made such as would permanently raise the level of the water in the river above its level as found at the time of the surveys.

TAUNTON. The Board received an application from the sewer commissioners of Taunton, Nov. 5, 1895, for advice relative to the disposal of the sewage of Taunton into the Taunton River without purification.

On March 5 a hearing was held at the office of the State Board of Health pursuant to a notice, at which the authorities of the city of Taunton and of the towns of Berkley, Dighton and Somerset were represented, the latter being opposed to the disposal of crude sewage of the city into the Taunton River. The hearing was continued and concluded on March 20, and on March 24 the Board sent the following reply to the sewer commissioners of Taunton:—

Boston, March 24, 1896.

The State Board of Health has considered your application with reference to the disposal of the sewage of the city of Taunton, and, before advising you definitely with reference to the most appropriate method of disposing of the sewage of the city, requests that you furnish an alternative plan for the disposal of the sewage by filtration through sand upon a suitable area available for the purpose.

On May 11 the sewer commissioners replied, suggesting the purchase of a certain tract or tracts of land in Berkley, near the Taunton River, for the purpose of using them as filtration areas for the sewage of the city. To this application the Board replied as follows:—

Boston, June 6, 1896.

In response to a request of this Board, dated March 24, 1896, that you submit a plan providing for the disposal of the sewage of Taunton on land, thus completing the plan of sewage disposal as proposed in the report accompanying your original application, this Board received from you, on May 11, a communication stating that you proposed to use land bordering on the Taunton River, opposite Blake's landing, and subsequently received from you a plan of the land, showing its outline and general elevation above high water in the river.

The Board has carefully considered the plan submitted, and has caused an examination of the land to be made by its engineers, and samples of the soil from a limited number of test pits located in various parts of the area to be analyzed.

These examinations indicate that there is an area of about 55 acres here having a sandy soil, which is situated at a sufficient elevation above average high water in the river to allow for underdrainage.

The information furnished by the limited number of test pits indicates that the soil of this area is generally very fine, and is composed of layers

of varying degrees of fineness,—a condition which would be unfavorable to the thorough aeration of the filter beds. A portion of the area, amounting to perhaps a third of the whole, contains a somewhat coarser sand, which is much better adapted to the purification of sewage.

The area as a whole will require a very large amount of preparation in order to bring it into suitable condition for the disposal of the sewage of Taunton by intermittent filtration. There is a considerable depth of loam upon the surface, which it will be necessary to remove, and a thorough system of underdrainage will be required. With thorough preparation and proper care of the filter beds, however, it is possible that the sewage of the city could be disposed of here for a time, unless there is a more rapid extension of the sewerage system than you now anticipate; but the cost of preparing the filter beds would be very large, as compared with the cost of preparing beds for this purpose where the material is coarse and porous; and, moreover, it does not appear that there is any considerable area of land in the immediate vicinity that can be utilized when an additional area becomes necessary. The material found in test pits dug in the smaller lots south of this area, plans of which were subsequently submitted, was found to be extremely fine, indicating that no considerable amount of sewage could be disposed of by filtration upon these lots.

There being much doubt as to the capacity of the proposed filtration area for the disposal of the sewage of the city of Taunton for a reasonable time in the future, and considering the large probable cost of properly preparing the filter beds, it seems very desirable that a much more thorough investigation be made of that part of your proposed plan which relates to the disposal of the sewage of the city upon land.

In view of all the circumstances, the Board does not, at present, approve of the proposed plan for the disposal of the sewage of Taunton, but advises a further investigation of the subject. In making these investigations, it is desirable that you determine, first, whether there is not some suitable area within the limits of the city of Taunton upon which it may be feasible to dispose of the sewage by intermittent filtration at a reasonable cost. If such an area cannot be found within the limits of the city, territory outside of the city limits should be considered, with a view to discovering some area suitable for the disposal of the sewage, which would not be objectionable if used for this purpose.

Should one or more suitable areas be found, a careful estimate should be made of the probable cost of preparing filter beds and disposing of the sewage upon them.

The Board will assist you, so far as it can, in these investigations, if you desire, and will make such examinations of filtering materials as may be necessary.

The sewer commissioners, on June 25, submitted a further plan for filtering the sewage of the city on land above the city and near the Taunton River. The Board replied to this communication as follows: -

Boston, July 6, 1896.

The State Board of Health received from you, on June 26, a communication setting forth in a general way a proposed system of sewerage and sewage disposal for the city of Taunton, accompanied by a plan showing a location for a pumping station on the north-easterly side of the New Bedford branch of the New York, New Haven & Hartford Railroad, between Ingell Street and the Taunton River, and a line of force main leading from the pumping station to a filtration area situated near the Taunton River, about a mile above the filter basin and pumping station of your water works.

A plan of the proposed filtration area was also received, showing an area of 65 acres, situated on the left or southerly bank of the river, just below the point where it is joined by the Cotley River. Other areas in the vicinity which might be made available for sewage-disposal purposes were indicated by your engineer.

By the present plan, it is understood that it is feasible to collect at the proposed pumping station the sewage from all of the thickly settled portions of the city, including the low districts near the river, which were omitted from the system proposed by the previous plan.

The Board has caused an examination of the proposed filtration area to be made, and samples of material taken from test pits in various parts of the area to be analyzed. The results of these examinations show that the material is for the most part well suited for the disposal of sewage by intermittent filtration, and there are other areas of land in the vicinity which also appear to be composed of porous material, judging from the appearance of the surface, which could be used for sewage-disposal purposes if necessary, so that it appears that a sufficient area of suitable land could probably be made available in this vicinity for the disposal of the sewage of the city of Taunton; but the situation of the proposed filtration area near the river, a short distance above the filter basin of the Taunton water works, is such that this Board cannot approve of the use of this area for sewage-disposal purposes so long as the effluent mingled with river water may be drawn through the filter basin of the water works for supplying the city with drinking water.

On August 18 the sewer commissioners again wrote to the Board, proposing to build a drain to convey the effluent away from the water works to a point farther down the river, and to construct an impervious dam between the filtration area and the river. To this communication the Board replied as follows:—

Boston, Sept. 10, 1896.

The State Board of Health received from you, August 20, a communication stating that you have made a more thorough examination of the proposed filtration area near Williams Street, and that you are satisfied that you can construct filter beds in such a manner that, by building a drain from the filtration area to the Taunton River, about 2 miles below the water works pumping station, you can be sure that none of the effluent can possibly reach the basin of the water works. You propose to construct the beds and to dispose of all of the drainage from the filtration area in this way. You state that an examination of the materials near the bank of the river along the filtration area shows that you can construct an impervious dam at this place.

Plans showing contour lines upon the proposed filtration area and the proposed line of the drain from the area to the Taunton River, with profile, were received with the application.

The Board has considered this plan, and concludes that, if all of the effluent can be removed from the proposed filtration field to a point of discharge in the Taunton River sufficiently below the water works filter basin to insure that no effluent can be drawn into the basin, and if the proposed dam can be so constructed as to prevent effluent or unfiltered sewage from entering the river otherwise than through the proposed drain, the sewage of the city of Taunton might be satisfactorily disposed of upon the area proposed; but no plans are furnished to show the method by which it is proposed to prevent the effluent from reaching the river opposite the filter beds. The Board, therefore, requests that you submit sufficient details of the scheme to show the character of the layers of material at the site of the proposed dam, and how you propose to construct the dam to make it impervious, and what method will be adopted to prevent accidental overflow of the sewage from the filtration area into the river above the water works filter basin. It is desirable also that you show the character of the layers of material underlying the proposed filter beds and the plan of the proposed underdrain system.

Van Choate Electric Company (Foxborough). The Van Choate Electric Company of Foxborough submitted to the Board for its approval, March 7, 1896, a plan of sewage disposal for their factory, having an outlet into a tributary of Mumford River. The Board replied to this application as follows:—

Boston, April 22, 1896.

The State Board of Health received from you, on March 7, an application for advice with reference to a proposed system of sewage disposal for the works of the Van Choate Electric Company, accompanied by a plan of a proposed settling tank and filter, having an outlet into a small brook, a tributary of the Mumford River.

The essential features of the plan are a settling tank for the removal of suspended matters from the sewage by sedimentation, and a filter bed 75 feet in length, 25 feet in width and 4 feet in depth, to be composed of stones and coarse gravel held between stone walls laid without mortar, through which sewage is to be passed laterally from an inlet chamber along one side of the bed to an effluent chamber on the opposite side, discharging thence into the brook. Sewage is to enter the inlet chamber through a pipe 4 feet above the bottom of the filter. Fourteen lines of 4-inch tile pipe are indicated upon the plan submitted, running from the inlet chamber on a level just below the pipe through which sewage enters it, across the filter, and terminating in the stones on the opposite side. It is proposed to lay these pipes with open joints, so that when sewage flows through them it may find an outlet into the filter in this way. It is understood that as many as 3,000 operatives may be employed in the works for which this system of sewage disposal is proposed.

The Board has carefully considered the plan submitted, and finds that it would be impracticable to purify the sewage from any considerable number of operatives by this plan.

The attention of the Board has been called to a filter constructed upon a plan similar to that proposed in the application submitted and intended to purify the sewage of a factory in Norwood. The results of a chemical analysis of a sample of the sewage applied to this filter and of a sample of the effluent show that no material purification of the sewage takes place in its passage through the filter; and, as the size of the filter proposed for the Van Choate Electric Company in proportion to the number of operatives would be about the same as at the Norwood works, there is no reason to expect that the results would be any different with the proposed filter than with the existing filter at Norwood.

The Board would therefore advise that you have a further investigation made, with a view to disposing of the sewage from your works in such a manner that it will not pollute the stream into which the effluent is finally discharged.

WESTBOROUGH INSANE HOSPITAL. The trustees of the Westborough Insane Hospital submitted a plan for the disposal of the sewage of that institution to the Board, April 7, 1896. This plan provided for the disposal of the sewage of the institution by filtration upon an area of land about a half mile from the hospital. The Board replied to this application as follows:—

Boston, May 7, 1896.

The State Board of Health received from you, on April 7, 1896, a plan for a proposed system of sewage disposal for the Westborough Insane Hospital. The plan provides for collecting the sewage of the hospital in a receiving basin or reservoir to be located about 250 feet north-west of the nearest portions of the buildings, from which an iron pipe sewer in the form of an inverted siphon is provided, to convey the sewage to a filtration area on the southerly side of Little Chauncy Pond, and about half a mile from the hospital buildings. Before entering the receiving reservoir the sewage will pass through a sludge tank intended for the removal of a portion of the solid matters from the sewage by sedimentation, and provision is made whereby the sludge can be drawn off from this tank by gravity and used as a fertilizer. The receiving reservoir will have a capacity of 20,000 gallons, and is designed to discharge its contents automatically, at intervals of several hours.

The area selected for the disposal of the sewage is the one referred to in previous communications of this Board as an area well adapted to the disposal of the sewage of this institution by intermittent filtration.

The Board has carefully considered the plan submitted, and has caused an examination of the proposed filtration area to be made by one of its engineers, and concludes that the proposed plan will provide satisfactorily for the disposal of the sewage of the hospital.

The screens indicated upon the plan have a somewhat limited area, but it is understood that your engineer proposes to provide larger screens than are indicated, and a larger screen area is very desirable, to avoid the necessity of excessive attention to keep them from clogging.

WHITMAN. The selectmen of Whitman applied to the Board, Aug. 13, 1896, for its advice relative to a system of drainage for Whitman, having a portion of its outlets into Hobart's Pond in that town. The Board replied to this application as follows:—

Boston, Nov. 5, 1896.

The State Board of Health received from you, on August 13, an application giving notice of your intention to introduce a system of drainage in the town of Whitman, accompanied by plans showing existing drains and

a proposed system of drainage for the remainder of the thickly settled portion of the town.

The Board has carefully examined the plans submitted, and has caused an examination of the territory to be made by one of its engineers. sizes of the proposed drains appear to be adapted to remove the surface and ground water from the watersheds which they are designed to serve, and the places of discharge of most of the drains are satisfactory. of the proposed drains, however, — one in Essex Street and another passing through Alden Street, - and one of the drains already built, which takes the drainage from the portion of the town in the vicinity of the junction of Temple and Washington streets, have outlets into Hobart's Pond. The water supply of Whitman is taken chiefly from a filter gallery upon the shore of the pond, and the Board is informed that the quantity furnished by the filter gallery is not at all times sufficient for the supply of the town, and the water is sometimes drawn directly from the pond.

While the drains are designed for surface water only, and are not intended to receive sewage, yet the experience with similar drains in thickly populated districts, especially where there is no sewer system, has shown that there is danger that unpurified sewage may find its way from cess-pools or from other receptacles for sewage or refuse matter into the drains and thence into the water supply of the town.

The Board is of the opinion that there is danger that the drainage discharged from these drains may be of such a kind as will corrupt or impair the quality of the water of the pond, upon the shore of which your filter gallery is situated and from which a part of your supply is taken directly, contrary to the provisions of chapter 80, section 96 of the Public Statutes.

Under existing conditions, the Board cannot advise the adoption of the portions of the proposed plan which provides for the discharge of drainage into Hobart's Pond or its tributaries, and advises that the matter be given further consideration, with a view to providing for the disposal of the drainage in such a manner that it cannot have an unfavorable effect upon the quality of your water supply.

Pollution of Ponds and Streams.

The following is the substance of the action of the Board relative to applications and information received in relation to the pollution of streams and ponds during 1896: -

Bradford. The water commissioners of Bradford applied to the Board, July 10, 1896, for its advice relative to the danger of pollution of their water supply in consequence of the existence of dwelling-houses on the shores of Johnson's and Chadwick's ponds, and the best mode of preventing it. The Board replied to this application as follows:—

Boston, Aug. 6, 1896.

Attention was especially called to drainage from houses on the shore of an arm of the pond, a short distance above the dam at its outlet. An examination of the conditions here shows that drainage from several houses is discharged directly into the pond. Water from the pond is used by the mills upon the stream below, and under ordinary conditions pollution discharged into this arm of the pond is drawn out with the water used by the mills, and at such times there is no danger of the pollution of the water supply of the town of Bradford by sewage from these houses. At times when no water is being drawn by the mills, there may be danger that pollution discharged into this arm would find its way into the main portion of the pond.

While danger to the purity of your water supply from this cause is remote, the Board considers that it is desirable to avoid it, if possible. This can be done either by diverting sewage from the houses in question to a point of discharge below the dam, or by causing a constant stream of water to flow out of the pond at all times sufficient to maintain a current from this portion of the pond toward the dam. It is understood that you have already taken action to prevent the threatened pollution from the summer residences within the watershed of Johnson's Pond.

IPSWICH. The water board of Ipswich applied to the Board of Health, April 25, 1896, for the advice of the Board relative to the best method of protecting its water supply from pollution in consequence of the existence of certain houses and stables on its immediate watershed. The Board replied to this application as follows:—

BOSTON, May 5, 1896.

The State Board of Health received from you, on April 25, an application for advice with reference to the protection of the purity of Dow's Brook Reservoir, your present source of water supply, from pollution by houses and barns located near the reservoir.

The Board has caused an examination of the locality to be made by one of its engineers, and finds that there are about nine houses and several stables situated within a short distance of the reservoir, drainage from which may enter the reservoir either directly or through small water courses in the vicinity of some of the buildings, and in some cases drains were found conveying household or stable drainage directly into the reser-

voir or a tributary water course. The soil in this region appears to consist largely of clay, and polluting matters discharged or deposited on the ground may flow or be carried by rain into the reservoir or the water courses near by, the nature of the soil being such that water does not penetrate it readily.

The Board is informed that there are cases of typhoid fever in some of the houses near the reservoir, and, as drainage or sewage from these houses may find its way into the reservoir with considerable directness, people using water drawn from the reservoir for drinking are exposed to very serious danger of infection with typhoid fever.

In a communication to the town of Ipswich relative to the use of Dow's Brook as a source of water supply, dated Feb. 1, 1894, the Board called attention to the danger of pollution of the water by the farm-houses upon the watershed of the proposed reservoir, and advised that care should be taken to prevent any pollution of the water by these farm-houses. The Board urges you to proceed at once to prevent the further pollution of the reservoir from this cause by diverting all sewage and other objectionable drainage from these buildings away from the reservoir and its tributaries, and disposing of it in some suitable manner, where it will not endanger the purity of your water supply.

The polluting matter which at present enters the reservoir tends to promote growths of organisms in the water by providing food upon which these organisms may subsist, and the removal of this pollution will tend to improve the character of the water in this respect also.

Manchester. The selectmen of Manchester, being directed by the town to report upon the best method of improving the condition of Central Pond in Manchester, and a plan having been reported to the town for cleaning out the pond and depositing the material so removed behind a retaining wall to be built for the purpose, submitted the question to the State Board of Health for its advice, Oct. 7, 1896. The Board replied to the application as follows:—

Boston, Nov. 9, 1896.

The pond in question is located in the central village of Manchester, and is formed by a dam at the mouth of Sawmill Brook. The dam is provided with a gate by means of which the pond can be emptied at low tide. Owing to leakage past the dam, it is said to be difficult to keep the pond full of water in the drier months of the year, and portions of the shore and bottom are consequently exposed at times.

The Board has caused an examination of the pond and its surroundings to be made by one of its engineers, at a time when the water was drawn off so that the condition of the bottom could be seen. It appears that the sewage from about sixteen buildings, including a small hotel and a stable, is discharged directly into the pond, and the bottom is covered with a thick layer of mud and organic matter, a portion of which has evidently come from the sewers and drains.

It is said that the pond gives off an offensive odor in the summer time, particularly when the bottom and shores are partially exposed, and that bubbles of gas rise to the surface of the water from the decomposing material upon the bottom.

By constructing a wall around the shores and cleaning the bottom of the pond, as proposed, a partial and temporary improvement in its condition would be made; but, in the opinion of the Board, to effect any permanent improvement in the sanitary condition of the pond, it is essential that the discharge of sewage into it, or any channel leading to it, be discontinued. After the sewage has been diverted and the mud and organic matter removed from the bottom, there is still some question whether so shallow a pond can be kept in unobjectionable condition in the midst of the village without frequent repetition of the cleaning process, and if the pond is to be preserved, it may be desirable to devise some means of flushing it out occasionally.

It is desirable that the pond be kept full of water at all times, and until the discharge of sewage into the pond is prevented and the organic matter removed from its bottom, some relief from offensive odors may be obtained by keeping the pond full, but the sewage should be diverted as soon as practicable.

The most favorable time for removing the organic matter from the bottom of the pond, in order that it may give the least offence to those living in the neighborhood, would be during the cooler weather of the fall and in the winter months.

The Board would also advise that, in providing a system of sewerage and sewage disposal for the buildings from which sewage is now discharged into the pond or its tributaries, you take into consideration the whole question of sewage disposal for the town, in order that any sewer or sewers constructed for the relief of this section may form a part of a general system for the village when such a system may be necessary.

NORTH Adams. The board of health of North Adams applied to the Board, July 18, 1896, for its advice relative to the propriety of acquiring two farms situated on the watershed of the public supply, for the purpose of protecting the supply from pollution. The Board replied to this application as follows:—

Boston, Aug. 6, 1896.

The State Board of Health has considered your request for advice as to the acquirement of two farms and the buildings thereon within the watershed of Notch Brook by the city of North Adams, and has caused an examination of the premises to be made by one of its engineers.

The situation of the buildings upon these farms is such that the natural drainage is into the proposed storage reservoir of the city of North Adams, and with present conditions there is danger that the reservoir may be polluted by sewage from these farms. It is, therefore, desirable that the city control them in such a way as to prevent the danger of pollution of the waters of the reservoir.

While it is possible, by the construction of suitable vaults and cesspools, to greatly reduce the danger of contamination from these buildings, efficient inspection will be necessary to accomplish this result. By causing the abandonment of the buildings, all danger to the water supply will be removed, and this is the best method of preventing danger to your water supply.

NORTHFIELD. The selectmen of Northfield applied to the Board, Nov. 12, 1896, for its advice relative to protecting the water of Mill Brook in that town from pollution. The Board replied to this application as follows:—

BOSTON, Dec. 10, 1896.

The State Board of Health received from you, on November 12, an application with reference to the protection of the purity of the waters of Mill Brook, so-called, in the town of Northfield, a stream which is used by several families as a source of domestic water supply, and has caused an examination of the locality to be made by one of its engineers.

From this examination it was found that sewage from the Northfield Hotel and from houses in the vicinity was entering the brook in such a way as to endanger the health of persons using the water for domestic purposes. The pollution of the stream by these houses could be prevented by diverting the sewage so that it would not enter the stream above the point from which water is taken for domestic purposes, or by disposing of it upon land, if a suitable place of disposal can be found in the vicinity, or in some other suitable way.

Farther up stream there are many houses situated near the stream, and in order to insure the suitability of the water for domestic purposes it will be necessary to make such provisions for the disposal of the sewage of these premises that no sewage may enter the stream.

The local board of health can prevent this pollution, if satisfied that

the present condition of the stream is a danger to the health of those using it.

Unless effective measures are taken to prevent all sewage from entering the stream, it cannot be regarded as a safe source of water supply for domestic purposes.

Peabody. The water commissioners of Peabody applied to the Board, March 4, 1896, for advice relative to the question of taking certain land lying upon the watershed of one of their reservoirs, for the purpose of protecting the purity of the water. The Board replied to this application as follows:—

Boston, April 2, 1896.

The State Board of Health received from you, on March 4, 1896, an application for advice with reference to protecting the purity of the water of the reservoir below Spring Pond, used as the direct source of water supply of Peabody, accompanied by a plan of a tract of land on the westerly side of the reservoir, which you state has recently been bought by a company and divided into lots which it is the intention of the company to sell for building purposes. The land in question lies between Lynn Street and the reservoir, and its general slope is from Lynn Street toward the reservoir. About half-way between the street and the reservoir, however, there is a small brook which flows northerly in the vicinity of the proposed Woodland Street, and discharges below the reservoir. Close to the easterly side of the brook there is a slight rise which forms a divide between the brook and the reservoir, and from this divide the land slopes directly to the reservoir.

Should houses be built upon the tract of land between Lynn Street and the brook, the surface drainage from this area would naturally flow off in the brook and be discharged below the reservoir; but drainage from the area between the brook and the reservoir would naturally flow directly to the reservoir. It would, therefore, be advisable for the town to control at least all land between the brook and the reservoir, to prevent the use of this area for any purpose that would tend to injure the quality of the water supply of the town; and the channel of the brook should be kept permanently open and its waters allowed to discharge as at present, below the reservoir. The desirability of controlling the land between the brook and Lynn Street depends largely upon the character of the soil and the direction in which the ground water flows, concerning which no information is If the soil is coarse and porous, and the available to the Board. ground water from this tract finds an outlet into the reservoir, the sewage deposited upon this territory might filter into the ground and find its way to the reservoir, and be objectionable.

Walpole (Neponset Reservoir). A communication was received from Uriah W. Boyden of Walpole, Feb. 7, 1896, remonstrating against the proposed discharge of sewage from the Van Choate Electric Works of Foxborough into the Neponset Reservoir. The Board replied to this communication as follows:—

Boston, March 6, 1896.

The State Board of Health has considered your communication with reference to the pollution of the Neponset Reservoir in Foxborough by sewage from the Van Choate Electrical Manufacturing Company's works, and has caused an examination of the premises to be made.

It is found that, while a drain for the removal of surface and ground water from the vicinity of the buildings has already been dug to the Neponset Reservoir and the construction of a sewage-disposal plant begun, the buildings are not yet completed and are not expected to be ready for occupancy until next fall, so that no sewage is at present being discharged from the works, and none is likely to be discharged for several months.

The attention of the company has been called to the provisions of chapter 375 of the Acts of 1888, a copy of which is enclosed.

WILLIAMSTOWN. The attention of the Board was called to the fact that a certain dwelling-house in Williamstown was so situated upon the watershed of the water supply of the town as to constitute a menace to the consumers of the water. The Board, therefore, sent the following letter to the Williamstown Water Company:—

Boston, Nov. 13, 1896.

It has been brought to the attention of the Board that there is a dwelling-house situated near the Flora Glen Reservoir, so-called, one of the sources of water supply of Williamstown, which is a menace to the purity of the water. The dwelling-house in question is located within 60 feet of the reservoir, and the arrangements are of such a character that a single case of typhoid fever occurring in this house might at any time, and before the danger was recognized, seriously endanger the health of the people of Williamstown.

While it appears that no water has been used from this reservoir for the supply of the town since last August, and that water is not likely to be used from it again until next summer, the Board would nevertheless urge that the house in question, together with any outbuildings within the watershed of the reservoir be removed without delay to some place outside of the watershed, and that any sewage or refuse matter that may have been deposited upon the ground about the buildings or at any place where there

is danger that it may find its way into the reservoir be carefully removed, so that the water from this reservoir may with safety be supplied to the town at all times.

WRENTHAM (PLAINVILLE). Messrs. Lincoln, Bacon & Co. of Plainville applied to the Board, Nov. 5, 1895, for its advice relative to the most practicable method of preserving the purity of the water of Bacon's Pond, the source of water supply of the village. The Board replied to this application as follows:—

Boston, March 6, 1896.

The State Board of Health received from you an application for advice as to the most practicable method of preserving the purity of the waters of Bacon's Pond, so-called, in the village of Plainville, from which water is drawn for the supply of the inhabitants of the village for domestic purposes. You state that the town of Wrentham has recently constructed a sewer on South Street in Plainville, which empties into Bacon's Pond, and is believed to be an injury to the quality of the water supply.

The Board has caused an examination of Bacon's Pond and its vicinity to be made by one of its engineers, and finds that the condition complained of is caused by the construction of a culvert to convey the drainage from the east side of South Street to the west side, from which it flows into Bacon's Pond. It appears also that a culvert formerly existed at this place, but it is said to have become obstructed before the reconstruction of the road, which took place last year. Water from the east side of South Street has probably always found its way into Bacon's Pond, either through the old culvert or by flowing over the street, and no material change has consequently been made in the conditions which formerly existed.

The watershed of Bacon's Pond contains a large population, and many of the houses are in the immediate vicinity of the pond. In the opinion of the Board, the danger of pollution entering the pond and the stream which feeds it from the population upon the watershed makes the water of the pond unsafe for drinking.

It is feasible to divert the water from the culvert into the outlet of the pond, whereby its drainage area would be reduced and the drainage from a considerable number of the houses on the watershed would be diverted to the stream below. There would still remain, however, a large population on the watershed of the pond; and, in the opinion of the Board, the diversion of the water conveyed by this culvert into the stream below would not render the pond a suitable source of supply for domestic purposes, on account of the large population which would still remain upon its watershed.

EXAMINATION OF WATER SUPPLIES.

EXAMINATION OF WATER SUPPLIES.

EXPLANATORY NOTE.

The systematic examination of the water supplies of the State was begun June 1, 1887, and has been continued up to the present time. The results of the investigations made during the first two years were published in a special report of the Board upon the Examination of Water Supplies (1890), and of those made during succeeding years in the annual reports of the Board beginning with the 1890 (Twenty-second Annual) report.

The special report contains a description of each of the water supplies in the State existing at the date of that report, and the annual reports contain descriptions of new works and changes in existing works.

In all of these reports an alphabetical arrangement by towns has been adopted. Sources of water supply are tabulated under the name of the town supplied, other waters under the name of the town in which they are situated. The analyses of water from the larger rivers not used as sources of water supply are given in a subsequent tabulation, headed "Examination of Rivers."

The method of making the chemical examinations remains unchanged, and the results are presented in the tables of this report in the same form as in the last one.

The samples of water are usually received at the laboratory from twenty-four to forty-eight hours after collection. All surface water and such samples of ground water as contain suspended matter are filtered through filter-paper before determining the color, the residue on evaporation and the albuminoid ammonia in solution. Some ground waters which are perfectly clear and colorless when drawn from the ground become turbid and colored on standing, in consequence of the oxidation of the iron which they contain. In these waters the residue on evaporation is determined without filtration, since this iron is an essential and not an accidental ingredient in the water. In the changes which accompany the oxidation of the iron in waters of this character, they become first cloudy (well described by the word milky) and finally deposit a precipitate of oxide of iron. In the cloudy condition they have a distinct color, which, while it does not have the same significance as in the case of surface waters, and is only a passing phenomenon, is, nevertheless, of interest as showing a color which the water may assume while the oxidation of the iron is in progress. When the iron is all oxidized and precipitated the water may become colorless again. In some cases, however, the iron occurs in combination with organic matter, forming a much more stable body. In such cases the water is of a brown color when first drawn from the ground, and, while the iron begins to oxidize soon after the water is exposed to the air, the process goes on slowly and the water may remain colored and iron continue to precipitate for a long time. Explanatory notes will be given in connection with the tables of analyses for waters containing iron.

The color of water is expressed by numbers which increase with the amount of color. The standard used is nesslerized ammonia, as described on page 531 of the

Special Report upon the Examination of Water Supplies, 1890, and on page 329 of the Annual Report for 1892. Boston water, as drawn from a tap at the Institute of Technology, had an average color in 1896 of 0.49. Other water supplies in the State have had an average color of from 0 to 1.34.

In cases where examinations of a source have been made with regularity for sev-

eral years, the averages of the chemical analyses of each year are given.

There was no change in the method employed in the microscopical examination of water between Nov. 6, 1890, and Dec. 1, 1895. The method employed between those dates is fully described in the Twenty-third Annual Report of the Board for the year 1891 (pages 395-421). Before Nov. 6, 1890, the methods employed were less perfect, so that a smaller proportion of the total number of organisms present in the water was separated from it and observed under the microscope; and, before drawing conclusions from a comparison of the microscopical examinations of waters made before and after this date, the explanatory note on page 70 of the Twenty-second Annual Report for 1890 should be read.

Since Dec. 1, 1895, the method for the microscopical analysis of water has been considerably improved by discarding the ordinary glass funnels previously employed, and substituting funnels which have been constructed with stems of equal calibre, to give equal rates of filtration, and with steeper sides, so that those organisms which are of a gelatinous character will be less liable to adhere to the sides of the funnel. By the use of these funnels variations in the numbers of organisms found, which may be caused by dissimilar slopes of the sides of the funnels and unequal rates of filtration, are avoided.

To indicate the amount of the so-called Zooglea observed, the number of individual masses is not counted, but an area equal to 2,500 square microns, or .0025 square millimeters, has been adopted as an arbitrary unit.

In publishing the results of the microscopical examinations the same system is followed as last year. The plants observed are classified in four groups, viz.: Diatomaceæ, Cyanophyceæ, Algæ and Fungi. The animals observed are grouped as Rhizopoda, Infusoria, Vermes and Crustacea.

The names of the different genera in each group are given with the numbers of each per cubic centimeter, except that, to avoid making the tables excessively long, they are omitted when present only in very small numbers. It is not feasible to make with regard to omissions a single rule which will apply to all cases, because it is desirable to include smaller numbers of animals than of plants, and of the larger animals than of animals generally. Moreover, there are exceptional cases in which it is desirable to indicate the presence of even very small numbers of the more important plants or animals. Two general rules, however, have been adopted in printing the results, viz.:-

1. All genera of plants are included in which the total number observed averages as much as 0.5 per cubic centimeter per month.

All genera of animals are included in which the total number observed averages as much as 0.1 per cubic centimeter per month.

The larger microscopic animals, such as some of the Crustacea, are included, even when present only in very small numbers.

Fractions are generally omitted from the table, the nearest whole number of organisms per cubic centimeter being given. Where the number observed is 0.5 or less, the fact that the organism was present is usually indicated by the abbreviation "pr.," but in the case of the larger organisms very small fractions are given.

ACTON.

ACTON.

The advice of the State Board of Health to the town of Acton with reference to taking water for a public water supply from the ground in the westerly part of the town may be found on pages 9 and 10 of this volume. Analyses of samples of water collected from test wells in this locality may be found on page 78 of the annual report for 1895.

The advice of the Board to citizens of East Acton with reference to taking water for the supply of that village from the water works of the town of Concord may be found on page 10 of this volume.

WATER SUPPLY OF ADAMS FIRE DISTRICT, ADAMS.

In 1895 a contract was made with the Adams Power Company to furnish an auxiliary supply of water to the Fire District from tubular wells situated at the Zylonite Works in the valley of the south branch of the Hoosac River, below Adams. Water from this source is pumped directly into the distributing system at times when the yield from the other sources is insufficient for the supply of the town. An analysis of a sample of water from one of these wells may be found on page 81 of the annual report for 1895.

Odor, none. — The first sample was collected from the reservoir; the second, from a brook entering the reservoir from the west; the third, from a brook entering the reservoir from the south-west; the last, from a brook entering the reservoir from the south-east.

Microscopical Examination.

An insignificant number of organisms was found in the first sample; in the other samples no organisms were found.

Odor, none. — The first sample was collected from a test well on the west bank of the Concord River, about 1,500 feet north of "Corner Bridge," between the villages of Billerica and North Billerica. The last sample was collected from a test well in the valley of Content Brook in East Billerica, about 400 feet west of the road from East Billerica to Billerica Centre. These samples were collected during an investigation relative to obtaining a water supply for the town of Billerica.

Microscopical Examination.

No organisms.

WATER SUPPLY OF BOSTON.

In 1896 the town of Natick, the densely populated portion of which is situated within the watershed of Lake Cochituate, completed a system of sewage disposal, and a few connections with the sewers were made in the latter part of the year. The sewage-disposal area is close to that used by the town of Framingham for a similar purpose, and outside of the limits of the Sudbury and Cochituate watersheds.

Works have also been completed for the filtration of drainage flowing from the underdrain of the Framingham sewer system, which was formerly discharged into one of the tributaries of Lake Cochituate. A filtration area for the disposal of this water has been prepared not far from the sewage pumping station and within the Cochituate watershed. The drainage may also be diverted into the sewage-receiving reservoir at the pumping station and disposed of in connection with the sewage, and a portion of the drainage has been disposed of in this way.

Work incidental to the construction of Dam No. 5 and the preparation of the large area of ground to be flowed by this reservoir has unfavorably affected the quality of the water of Stony Brook and Reservoir No. 3, as in the two previous years, and the use of water from Reservoir No. 3 has been avoided as far as possible.

Sudbury River Supply. — Chemical Examination of Water from Indian Brook, at Head of Reservoir No. 6, Hopkinton.

Note to analyses of 1896: Odor, vegetable and occasionally mouldy, becoming somewhat stronger on heating. The iron was determined in eleven samples, the average amount found being .0155 parts per 100,000.—The samples were collected from the reservoir, near the dam. For monthly record of height of water in this reservoir, see table at end of Boston analyses.

^{*} June to December.

Note to analyses of 1896: Odor, generally distinctly vegetable and mouldy, becoming stronger on heating. - The samples were collected from the brook, at its entrance into Reservoir No. 4.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 57.

^{*} June to December.

Note to analyses of 1896: Odor, vegetable; generally stronger on heating. The iron was determined in nine samples, the average amount in parts per 100,000 being .0138. — The samples were collected from the reservoir, near the gage-house. Nos 16172, 16528 and 16904 were collected 8 feet beneath the surface, and the others 1 foot beneath the surface. For monthly record of height of water in this reservoir, see table at end of Boston analyses.

[†] Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

Sudbury River Supply.— Microscopical Examination of Water from Reservoir No. 4, Ashland.

^{*} June to December.

Note to analyses of 1896: Odor, vegetable and occasionally mouldy, becoming stronger on heating. — The samples were collected from the river, near the old dam at the upper end of Reservoir No. 2, at a depth of 1 foot beneath the surface.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 92.

Sudbury River Supply. — Chemical Examination of Water from Reservoir No. 2, Framingham.

^{*} June to December.

Note to analyses of 1896: Odor, faintly vegetable, becoming stronger on heating. — The samples were collected from the reservoir, near the gate-house, at a depth of 8 feet beneath the surface. For monthly record of height of water in this reservoir, see table at end of Boston analyses.

^{*} June to December.

Note to analyses of 1896: Odor, generally distinctly vegetable and occasionally mouldy.—The samples were collected from the brook, about 50 feet below the first road above Reservoir No. 3, at a depth of 1 foot beneath the surface.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 132.

Sudbury River Supply. — Chemical Examination of Water from Reservoir No. 3, Framingham.

^{*} June to December.

Note to analyses of 1896: Odor, distinctly vegetable, occasionally mouldy.— The samples were collected from the reservoir, near the gate house, at a depth of 8 feet beneath the surface. For monthly record of height of water in this reservoir, see table at end of Boston analyses. The quality of the water of this source and of Stony Brook may have been affected during much of the year by work incident to the construction of Reservoir No. 5 on Stony Brook, above Reservoir No. 3.

Sudbury River Supply.— Microscopical Examination of Water from Reservoir No. 3, Framingham.

WATER SUPPLY OF BRADFORD.

Works for supplying the town of Bradford with water from Johnson's Pond, in the towns of Boxford and Groveland, were completed in March, 1896, and the former sources of supply, consisting of wells on Porter's Island and the southerly shore of the Merrimack River below Bradford and Haverhill, were abandoned on account of the poor quality of the water. The deterioration of the water of these wells, as shown by chemical analyses, has been noted in the previous reports.

Johnson's Pond, the new source of supply, has an area of 222 acres, a maximum depth of 32 feet and an average depth of 14 feet. Its total capacity is about 1,000,000,000 gallons. The shores of the pond and a large portion of the bottom are sandy. In the deeper portions the bottom is said to be muddy, but the area of muddy bottom is said to be small compared with the total area of the pond. The area of the watershed, as measured on the State map, is about 4.9 square miles, including the area of the pond and of Chadwick's Pond, which is included within the watershed. The watershed is for the most part high gravelly land, with a very limited

BRADFORD.

area of swamp land, and the population on the watershed is small in comparison with its area. Several houses, occupied for the most part in the summer season, are located near the shores of the pond, and the advice of the State Board of Health with reference to the protection of the purity of the water supply from danger of pollution by these houses may be found on pages 70 and 71 of this volume.

Odor, unpleasant. — The sample was collected from the pond, at its outlet.

Microscopical Examination.

An insignificant number of organisms was found in this sample.

BRAINTREE.

WATER SUPPLY OF BRAINTREE.

The advice of the State Board of Health to the town of Braintree relative to increasing the water supply of the town by taking water from tubular wells located on the shore of Little Pond, a short distance north of the present filter-gallery, may be found on pages 11 to 14 of this volume. Analyses of samples of water from the filter-gallery and from tubular test wells along the easterly shore of the pond, near the filter-gallery, are given in the following tables:—

Chemical Examination of Water from the Filter-gallery of the Braintree Water Works.

Odor, decidedly tarry and unpleasant. — The samples were collected from an underdrain, at its outlet into Salisbury Plaiu River, at Factory Village.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 513, consisting chiefly of *Crenothrix*.

Note to analyses of 1896: Odor, distinctly vegetable and mouldy, becoming stronger on heating.

— The samples were collected from the brook. The quality of the water of this source and of Stony Brook Reservoir may have been affected during much of the year by work incident to the construction of a storage reservoir upon Hobbs Brook, above the points where the samples were collected.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 84.

CAMBRIDGE.

^{*} October.

Note to analyses of 1896: Odor, frequently mouldy or musty, often none; on heating, somewhat stronger. — The samples were collected from the underdrain, at its outlet.

Microscopical Examination.

The total number of organisms per cubic centimeter found in these samples was as follows: No. 16891, 295; No. 16080, 1,640; No. 16240, 1,220; No. 16420, 1,844; No. 16596, 4,518; No. 16765, 1,204; No 16993, 104; No. 17199, 90; No. 17419, 113; No. 17650, 4,064; No. 17840, 0; No. 18043, 900. The organisms found consisted chiefly of *Crenothrix*.

FRANKLIN.

WATER SUPPLY OF FRANKLIN. - FRANKLIN WATER COMPANY.

The reply of the State Board of Health to an application from the selectmen of Franklin with reference to the quality of the water supplied by the Franklin Water Company may be found on pages 15-17 of this volume. Analyses of samples of water collected during the investigation made by the Board are given in the following tables:-

Odor, none A faintly earthy odor was observed in the third and fifth samples when heated.—
The first sample was collected from a tap in the pumping station, while pumping; the next two, from the small well; the last two, from the large well. Water is pumped from the small well, into which water from the large well flows by gravity.

Microscopical Examination.

No organisms.

Odor, none, becoming distinctly clayey on heating. — The samples were collected from a tubular well, sunk in rock to a depth of 223 feet. The well is situated on the summit of a hill, near the factory of Hildreth Bros.

Microscopical Examination.

No organisms.

WATER SUPPLY OF HATFIELD.

Population in 1895, 1,262. The works are owned by the town, and were completed in August, 1896. The source of supply is Running Gutter Brook, in the westerly part of the town, on which a small storage reservoir has been constructed. Water is conveyed to the village of Hatfield by gravity through four miles of eight-inch cast-iron pipe. The watershed of the reservoir is largely wooded, and contains no dwelling-houses. The reservoir was prepared for the storage of water by removing all the organic matter from the sides and bottom. Service pipes are of galvanized iron.

The advice of the State Board of Health to the town of Hatfield relative to taking water from Field's Brook to supply that portion of the town known as North Hatfield may be found on page 18 of this volume.

^{*} June to November.

Note to analyses of 1896: Odor, vegetable, occasionally none. —— No. 16856 was collected from the lake; the others, from a faucet at the pumping station. During the year 1896 144,000,000 gallons of water were pumped from the Millvale Reservoir on East Meadow Brook into Kenoza Lake. For monthly height of water in this lake, see table on pages 168 and 169.

The advice of the State Board of Health to the Haverhill Real Estate Improvement Company, with reference to the use of water from a well situated under a building owned by the company, may be found on pages 18 and 19 of this volume. Analyses of samples of water taken from the well at different times are given in the following table:—

Chemical Examination of Water from the Well of the Real Estate Improvement Company, Haverhill.

Odor of the first sample, faintly vegetable; of the second, faintly vegetable, becoming distinctly vegetable and mouldy on heating; of the third, none, becoming distinctly mouldy on heating. — The first sample was collected from a faucet in the building owned by the Real Estate Improvement Company in Haverhill, and probably represents water from the Haverhill water works; the second sample was collected from a blow-off valve beneath the building, and probably represents water from a well beneath the building, driven through rock to a depth of 226 feet, mixed with water from the city water works; the third sample was collected from the blow-off valve beneath the building after a considerable quantity had been pumped from the well into the pipes, and probably represents chiefly water from the well.

Microscopical Examination.

The total number of organisms per cubic centlmeter found in these samples was as follows: No. 16671, 204; No. 16891, 8; No. 17266, 0.

^{*} August, two samples.

Note to analyses of 1896: Odor in July and September, none; at other times, vegetable. — The first four samples were collected from a faucet at the pumping station, while pumping; the last two were collected from faucets in the town.

Microscopical Examination.

An insignificant number of organisms was found in these samples.

Odor of the first sample, distinctly clayey; of the second, distinctly grassy. — The first sample was collected from a faucet in the village supplied from a spring on the hillside, south of Westfield River; the last, from a spring near the road from Norwich bridge to Chester Center, about 2½ miles from the village of Huntington.

Microscopical Examination.

An insignificant number of organisms was found in No. 16120; no organisms were found in the other sample.

Chemical Examination of Water from Cook or Roaring Brook and from Taylor Brook, in Huntington.

Odor, none. — The samples were collected from tubular test wells in the valley of Mother Brook in Dedham, near the line between the towns of Hyde Park and Dedham. — The first sample was collected from a well on the northerly side of the brook; the last two, from a well on the southerly side of the brook.

Microscopical Examination.

[†] August and September.

IPSWICH.

WATER SUPPLY OF IPSWICH.

The advice of the State Board of Health to the water board of Inswich, relative to the protection of the purity of the water of Dow's Brook storage reservoir, may be found on pages 71 and 72 of this volume. Analyses of samples of water collected from several small streams entering the reservoir are given in the following tables: -

Chemical Examination of Water from Dow's Brook above the Storage Reservoir of the Ipswich Water Works.

Note to analyses of 1896: Odor, generally faintly vegetable, sometimes none. All of the samples had vegetable odors when heated. - The samples were collected from the brook, at its entrance to the storage reservoir.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 25.

Odor of the fourth sample, none; of the others, generally distinctly vegetable, sometimes mouldy, becoming stronger on heating. — The samples were collected from the brook, near its junction with Dow's Brook, below the storage reservoir of the Ipswich water works. This brook is not used as a source of water supply.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 255.

^{*} Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

Odor of the first three and last samples, none; of the fourth, very faintly vegetable, becoming stronger on heating; of the fifth, none, becoming faintly earthy on heating.—The last sample was collected from a faucet in the town; the others, from a faucet at the pumping station.

Microscopical Examination.

The total number of organisms per cubic centimeter found in these samples was as follows: No. 15947, 20; No. 16276, 782; No. 16600, 2,500; No. 16611, 1,250; No. 17587, 4,000; No. 17867, 960; consisting chiefly of *Crenothrix*.

KINGSTON.

Chemical Examination of Water from Pine and Howard Brooks in Kingston.

Odor of the first sample, faintly vegetable; of the second, faintly vegetable, becoming distinctly unpleasant on heating. — The first sample was collected from Pine Brook, at the first road crossing above its junction with Howard Brook; the last, from Howard Brook, at the first road crossing above its junction with Pine Brook, and just below a small mill-pond. The samples were collected in connection with an investigation for an additional water supply for Brockton.

Microscopical Examination.

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 17137, 128; No. 17138, 143.

Chemical Examination of Water from Tubular Test Wells in the Valley of Furnace Brook, Kıngston.

Odor, none. — The first three samples were collected from individual wells in a group of seven wells in the vailey of Furnace Brook, below the dam of Maglathlin's tack factory. No. 16599 was collected from the well nearest the dam, and No. 16598 from the well farthest down the stream. Samples Nos. 16693, 16721, 16735 and 1671 were collected during a pumping test made by pumping from three wells about 600 feet below the tack factory, at a rate said to be equivalent to 245,000 gallons perday. The first of these samples was collected on the first day of the test, about two hours after pumping began; the second, after pumping thirty-nine hours continuously; the third, after pumping continuously for four days; and the last, after pumping ten days. Sample No. 16772 was collected from a test well near the group of wells connected with the pumps, just after pumping was discontinued; and sample No. 16773 was collected from a test well about 300 feet below the tack factory dam, just after the pumping test from the wells farther down the valley had been discontinued.

Microscopical Examination.

An insignificant number of organisms was found in No. 16721; no organisms were found in the remaining samples.

WATER SUPPLY OF LANCASTER.

(See Clinton.)

LAWRENCE.

WATER SUPPLY OF LAWRENCE.

The following tables contain analyses of the unfiltered Merrimack River water, and of the filtered water at the pumping station and at the distributing reservoir. The results of more extended chemical and biological examinations of the water before and after filtration through the sand filter may be found in a subsequent portion of this report, in the chapter on "Filtration of Water."

Chemical Examination of Water from the Merrimack River above Lawrence, opposite the Intake of the Lawrence Water Works.

^{*} June to November.

Note to analyses of 1896: Odor, vegetable or musty. - The samples were collected from the river, opposite the intake of the Lawrence water works, about 1 foot beneath the surface. For a record of the quantity of water flowing in the river on dates when samples of water were collected for analysis, see page 194. For a comparison of the analyses of the river water at Lowell and Lawrence for a series of years, sec "Merrimack River," in the chapter on "Examination of Rivers."

[†] January to May.

[‡] August to December.

[§] July to December.

Note to analyses of 1896: Odor, generally vegetable or earthy, occasionally none. — The samples were collected from a faucet in the check-valve, just beyond the pump, and represent water from the river which has passed through the sand filter, mingled with a small amount of ground water, containing considerable free ammonia and iron.

Microscopical Examination.

The total number of organisms per cubic centimeter found in these samples was as follows: No. 15933, 1,600; No. 16101, 10; No. 16286, 65; No. 16470, 65; No. 16646, 324; No. 16821, 120; No. 17042, 800; No. 17250, 80; No. 17484, 700; No. 17696, 60; No. 17893, 800; No. 18142, 10; consisting chiefly of Crenothric.

Odor of the last three samples, none; of the others, vegetable and earthy, occasionally mouldy, becoming somewhat stronger on heating.— The samples were collected from a faucet at the gate-house, and represent water flowing out of the reservoir. The reservoir is supplied with filtered water.

Microscopical Examination of Water from the Distributing Reservoir of the Lawrence Water Works.

Note to analyses of 1896: Odor of Nos. 16613 and 17972, vegetable or earthy; of the others, none.

The samples were collected from a faucet in the village.

Microscopical Examination.

An insignificant number of organisms was found in these samples.

LEICESTER.

Odor, none, becoming distinctly earthy on heating. — The sample was collected from the underdrain in Pine Street.

WATER SUPPLY OF LEOMINSTER.

During the year 1896 the sources of water supply of the town of Leominster were increased by the taking of the water of Fall Brook and the construction of a storage reservoir upon this stream in the southerly portion of the town.

The reservoir, when full, has an area of 82.5 acres, a capacity of about 386,000,000 gallons, an average depth of 14.3 feet and a maximum depth of 28 feet. The area flowed consisted chiefly of pasture and wood land, though a portion was under cultivation. In the lower portion of the valley there was a considerable area of meadow and swamp land, where the mud was found to extend to a considerable depth. The reservoir was prepared by the removal of all the stumps, soil and vegetable matter from the area flowed, with

LEOMINSTER.

the exception of about 19.5 acres of the swamp and meadow land in the lower portion of the area where the mud was quite deep, which was covered with gravel to a depth of from 15 to 18 inches after the removal of the trees and bushes. Storage in this reservoir was begun in the latter part of October.

The watershed of the reservoir has an area of 1.26 square miles and contains a very small population. The slopes are steep and there is very little swamp land on the area.

Chemical Examination of Water from Haynes Reservoir, Leominster.

^{*} June to December.

Note to analyses of 1896: Odor, vegetable or sweetish; in July, also unpleasant. A sweet, grassy odor was developed in most of the samples on heating.——The samples were collected from the reservoir.

Odor, generally distinctly vegetable; in April, mouldy. — The samples were collected from the brook, at entrance to storage reservoir.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 81.

Chemical Examination of Water from the Vine Brook Storage Reservoir of the Lexington Water Works.

Odor of the last sample, distinctly unpleasant; of the others, none. — The first three samples were collected from faucets in the town, and the others from a faucet at the pumping station, while pumping.

Microscopical Examination.

No organisms were found in Nos. 16302 and 17564; an insignificant number was found in the others.

LOWELL.

WATER SUPPLY OF LOWELL.

A third system of tubular wells for supplying water to the city of Lowell was completed during the year 1896. The wells are located on the north bank of the Merrimack River, between the river and the Pawtucket Boulevard, about a quarter of a mile above the Lowell dam. The system consists of 169 two and one-half inch wells, varying in depth from 27 to 40 feet, and situated at a distance of from 150 to 350 feet from the bank of the river. Pumping from this plant was begun Feb. 28, 1896. The tubular wells are said to have furnished all the water supplied to the city from Feb. 22, 1896, to the end of the year.

Chemical Examination of Water from the Merrimack River above Lowell.

^{*} June to December.

Note to analyses of 1896: Odor, none. — The samples were collected from the wells, which are locally known as the "Cook" wells. No water was drawn from these wells from June 1 to October 9.

Microscopical Examination.

No. 18125. Fungi, Crenothrix, 50.

No organisms were found in the remaining samples.

^{*} Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

Note to analyses of 1896: Odor, faintly vegetable or none. — The samples were collected from a faucet at the pumping station, while pumping. These wells are locally known as the "Hydraulic Construction Company's" wells.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 145, consisting chiefly of Crenothrix.

Odor, none. — The samples were collected from a faucet at the pumping station, while pumping. The wells are locally known as the "Boulevard" wells.

Microscopical Examination.

An insignificant number of organisms was found in Nos. 17236 and 17472; no organisms were found in the other samples.

WATER SUPPLY OF LUDLOW.

(See Springfield.)

WATER SUPPLY OF LYNN AND SAUGUS.

During 1896 the capacity of the works for supplying water to the city of Lynn was increased by the completion of a storage reservoir upon Hawkes Brook. This reservoir has an area of 75 acres, a maximum depth of 25 feet and an average depth of 12.3 feet. Its capacity is about 300,000,000 gallons. The reservoir was prepared for the storage of water by the removal of stumps, soil and vegetable matter over a large portion of its area, but over a considerable portion of the area, on account of the depth of the mud, this material was not removed, but these areas are said to have been covered with gravel to a depth of about 18 inches.

The area of the watershed, including the reservoir, is about 1.9 square miles and contains a small population.

^{*} June to December.

Note to analyses of 1896: Odor, generally vegetable, sometimes also mouldy or grassy, rarely none.

— The samples were collected from the pond, near the gate-house, 1 foot beneath the surface. For monthly height of water in this pond, see page 219.

Note to analyses of 1896: Odor, generally distinctly vegetable and frequently sweet and grassy.—
The samples were collected from the pond, near the gate-house, 1 foot beneath the surface. For monthly height of water in this reservoir, see page 219.

LYNN AND SAUGUS.

^{*} The water in these ponds is sometimes raised somewhat above ordinary high water.

MALDEN, MEDFORD AND MELROSE.

WATER SUPPLY OF MALDEN, MEDFORD AND MELROSE.

The water of Spot Pond was at high-water level in April, 1896, for the first time since April, 1891. The filling of the pond was due to the decrease in the draft from it caused by the use of water from auxiliary sources of supply introduced by the municipalities using water from the pond.

Chemical Examination of Water from Spot Pond, Stoneham.

^{*} May to December.
† Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

Note to analyses of 1896: Odor, distinctly vegetable and mouldy, occasionally unpleasant. — The samples were collected from the pond. For monthly height of water in the pond, see page 222.

Averages by Years.

^{*} Three samples in November and December.

Note to analyses of 1896; Odor, none. — No. 17620 was collected from a drinking fountain; the other samples were collected from a faucet at the pumping station.

Microscopical Examination.

An insignificant number of organisms was found in Nos. 16027, 16374 and 17141; no organisms were found in the other samples.

[†] June and October.

Odor of the last sample, distinctly disagreeable; of the others, none.

Microscopical Examination.

An insignificant number of organisms was found in No. 16296; no organisms were found in the other samples.

WATER SUPPLY OF MARLBOROUGH.

During the spring of 1896 about 13,000,000 gallons of water were pumped from Millham Brook, above the storage reservoir, into Lake Williams, from which the supply of the city is drawn. No water was used from the Millham Brook storage reservoir.

Chemical Examination of Water from Lake Williams, Marlborough.

^{*} June to December.

Note to analyses of 1896: Odor, distinctly vegetable. — The second sample was collected from the lake, and the other samples from a faucet at the pumping station.

Microscopical Examination.

The total number of organisms per cubic centimeter found in each of these samples was as follows No. 16039, 46; No. 16575, 375; No. 17160, 78; No. 17800, 58.

[†] March and April.

Chemical Examination of Water from the North Branch of Millham Brook, near its Entrance to the Millham Brook Storage Reservoir, Marlborough.

Odor of the first sample, none; of the second, faintly vegetable, becoming distinctly vegetable and mouldy on heating. — The first sample was collected from a faucet in the town, and the last from the pond. The sample collected in the village represents pond water mixed with a large amount of ground water which finds its way into the pipe leading from the pond to the pumping station.

Microscopical Examination.

Odor, none. — The sample was collected from a spring near Vine Brook, about one-third of a mile above North Street. This spring is used as a source of water supply by a large straw factory and by a portion of the village of Medfield.

Microscopical Examination.

No organisms.

WATER SUPPLY OF MEDFIELD INSANE ASYLUM.

The advice of the State Board of Health to the trustees of the Medfield Insane Asylum with reference to an additional water supply for the asylum may be found on page 24 of this volume. Analyses of samples of water collected from Farm Pond in Sherborn during the investigations made by the Board may be found under "Sherborn" in this report.

WATER SUPPLY OF MEDFORD.

Water from Wright's Pond was used for the supply of the city from the beginning of the year until May 28, 1896, at which time its use was discontinued, owing to the unsatisfactory quality of the water.

For information regarding the water supply of Medford from Spot Pond and for analyses of samples of water from the pond, see pages 220 to 222.

Note to analyses of 1896: Odor, none. - The samples were collected from the underdrain in Boston Avenue, near the Mystlc River.

Microscopical Examination.

No. 16246. Miscellaneous, $Zo\ddot{c}gl\varpi a$, 150. No. 17860. Fungi, Crenothrix, 350. Miscellaneous, $Zo\ddot{c}gl\varpi a$, 100. Total, 450.

No organisms were found in the remaining sample.

MEDWAY.

MEDWAY.

The advice of the State Board of Health to the town of Medway with reference to the introduction of a water supply from sources near the village of West Medway may be found on page 25 of this volume.

The advice of the Board to the Medway Water Company with reference to securing a supply of water from wells located in the valley of the Charles River in the easterly part of Medway may be found on pages 25 to 27 of this volume.

Analyses of samples of water collected from various sources in the town during the investigations are given in the following tables. An analysis of a sample of water from the Charles River at Medway may be found in the chapter on "Examination of Rivers," in a subsequent portion of this report.

[Parts per 100,000.]

Odor, none. — The first sample was collected from a tubular test well on the easterly side of Chicken Brook and about 100 feet north of Mechanic Street in West Medway, near the site of an old dam; the last sample was collected from a spring about 500 feet west of Chicken Brook, a short distance above the site of the old dam.

Microscopical Examination.

An insignificant number of organisms was found in sample No. 16833; no organisms were found in the other sample.

Odor, none.—The samples were collected from tubular test wells on the south bank of the Charles River, in the easterly part of the town of Medway, as follows: the first two samples, from a test well about 500 feet below the Ray & Wilson dam; the next two samples, from a well about 120 feet further down the stream; and the last three samples, from a well about 700 feet below the Ray & Wilson dam. Each of the wells was about 60 feet from the river. The last sample was collected after pumping continuously from the well for one hundred and four hours, at a rate of 70 gallons per minute.

Microscopical Examination.

No organisms.

WATER SUPPLY OF MELROSE.

For information regarding the water supply of Melrose from Spot Pond and for analyses of water from the pond, see pages 220 to 222. The auxiliary supply from tubular wells in the valley of Spot Pond Brook, which was used during the years 1894 and 1895, was abandoned in May, 1896, since which time the entire supply for the town has been drawn from Spot Pond.

Chemical Examination of Water from Tubular Wells in the Valley of Spot Pond Brook, near Wyoming Avenue, used as an Additional Source of Water Supply for Melrose.

Odor, distinctly vegetable. — The first sample was collected from Back River, about 600 feet above Cobbler's Brook; the last two samples, from the millpond at Sargent's Mill.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 59.

Odor, faintly vegetable, becoming somewhat stronger on heating. — Nos. 17723 and 17912 were collected from the west branch of Cobbler's Brook, at the first road crossing above the old Tukesbury dam; the remaining samples were collected from the brook, at the Tukesbury dam.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 20.

WATER SUPPLY OF METHUEN.

Chemical Examination of Water from the Tubular Wells of the Methuen Water Works.

* June to December.

† January to June.

Note to analyses of 1896: Odor of No. 16650, sweet; of No. 17820, decidedly unpleasant; of the others, none. — No. 17363 was collected from the lake; the remaining samples, from a faucet in the pumping station.

Microscopical Examination.

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 15907, 0; No. 16294, 31; No. 16650, 86; No. 17030, 125; No. 17363, 704; No. 17820, 241.

MONTAGUE.

MONTAGUE.

The advice of the State Board of Health to the water supply committee of the village of Miller's Falls, relative to the introduction of a public water supply for the village of Miller's Falls, in the towns of Montague and Erving, may be found on pages 30 and 31 of this volume. Analyses of samples of water collected during the investigation of the proposed sources of supply may be found on page 236 of the annual report for 1895.

WATER SUPPLY OF NAHANT.

(See Swampscott.)

WATER SUPPLY OF NANTUCKET. — WANNACOMET WATER COMPANY.

^{*} June to December.

Note to analyses of 1896: Odor, distinctly vegetable and mouldy. — The samples were collected from the conduit, at its entrance to the receiving reservoir, and represent water from the storage reservoir. For heights of water, see page 251.

[†] Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

^{*} June, 1887, to May, 1888.

Note to analyses of 1896: Odor, occasionally vegetable, frequently none. — The samples were collected from a faucet at No. 2 State Street.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 72.

[†] The very high chlorine present in the water in 1893 was due to the use at times of water from the Merrimack River, which contained a small amount of sea water.

WATER SUPPLY OF NEWTON.

Chemical Examination of Water from a Faucet at the Newton Water Works

Pumping Station.

NORTH ADAMS.

WATER SUPPLY OF NORTH ADAMS.

During the years 1895 and 1896 a reservoir was constructed on Notch Brook, one of the sources of water supply of the city of North Adams. The reservoir was prepared for the storage of water by the removal of soil and vegetable matter from its bottom, and has an area when full of about 12.5 acres and a storage capacity of 90,000,000 gallons. The watershed of the reservoir consists chiefly of steep slopes covered with wood, and is uninhabited.

The advice of the State Board of Health to the board of health of North Adams, relative to the protection of the purity of the Notch Brook supply by the removal of houses on the watershed of the reservoir, may be found on pages 73 and 74 of this volume.

Chemical Examination of Water from Notch Brook Storage Reservoir, North Adams.

^{*} August to December.

Note to analyses of 1896: Odor, faintly vegetable or none. — The samples were collected from the stream, just above the reservoir.

Microscopical Examination.

The average number of organisms per cubic centimeter found in these samples was 21.

Chemical Examination of Water from the Middle Storage Reservoir of the Northampton Water Works on Roberts' Meadow Brook, collected near the Surface.

Odor, distinctly vegetable. — The first sample was collected from Mill Brook, at first road crossing above Main Street, and above the point where the sewage from a hotel enters the stream; the second, from Mill Brook, just above Main Street, at the point where a water supply for several familles is taken.

Microscopical Examination.

The total number of organisms per cubic centimeter found in these samples was as follows: No. 17967, 21; No. 17968, 12.

NORWOOD.

WATER SUPPLY OF NORWOOD.

Reference was made in the last annual report to the disagreeable taste and odor in the water from Buckmaster Pond, caused by the organism *Uroglena*. Trouble from this cause continued through the spring of 1897, but ceased early in the summer.

Chemical Examination of Water from Buckmaster Pond, Dedham.

Note to analyses of 1896: Odor, generally none, occasionally vegetable. In September a fishy odor was observed. - The samples were collected from the reservoir.

Microscopical Examination.

An insignificant number of organisms was found in these samples, with the exception of the sample collected in September, in which were found the following organisms: Infusoria, Dinobryon cases, 44; Uroglena, 8. Total, 52.

WATER SUPPLY OF PEABODY.

The organism *Uroglena* appeared in the water of Brown's and Spring ponds in the early part of 1896, giving the water a disagreeable taste and odor, which was especially noticeable in Spring Pond. The water of these ponds passes into a lower basin before entering the pipe to the town, but no organisms were found in the samples of water collected from this source.

The advice of the State Board of Health to the town of Peabody with reference to the desirability of taking certain lands on the watershed of the lower basin, in order to protect the water from contamination, may be found on page 75 of this volume.

Odor of the first four samples, very faint or none; of the fifth, distinctly grassy or mouldy; of the last, faintly vegetable. — The first and second samples were collected from the central portion of the lake, at the surface and bottom, respectively; the third and fourth samples were collected from the northerly end of the lake, at the surface and bottom, respectively; the fifth and slxth samples were collected from the southerly end of the lake, at the surface and bottom, respectively. These analyses were made during an investigation with reference to an additional water supply for the city of Brockton.

Odor of the first sample, none, becoming faintly grassy on heating; of the last, distinctly vegetable.

The first sample was collected from the centre of Oldham Pond, near the surface; the second, from Tubbs Meadow Brook, at its entrance into Silver Lake.

Microscopical Examination.

The total number of organisms per cubic centimeter found in these samples was as follows: No. 17013, 51; No. 17132, 28.

WATER SUPPLY OF PITTSFIELD.

The advice of the State Board of Health to the city of Pittsfield with reference to taking an additional water supply from certain brooks in the vicinity of the city may be found on pages 33 to 35 of this volume. Analyses of samples of water collected from these brooks and other sources may be found on pages 277 to 279 of the annual report for 1895.

Chemical Examination of Water from Sacket Brook Reservoir, Pittsfield.

Odor in June, faintly vegetable and mouldy; at other times, none. — The samples were collected from the reservoir.

Microscopical Examination.

PLYMOUTH.

WATER SUPPLY OF PLYMOUTH.

The organism *Uroglena* appeared in the water of Little South Pond in the latter part of 1895, and was present until late in the spring of 1896, giving trouble during much of this time on account of the fishy taste which it imparted to the water. The advice of the State Board of Health to the water commissioners of the town of Plymouth relative to improving the quality of the water supply of the town may be found on pages 35 to 37 of this volume.

WATER SUPPLY OF READING.

In July, 1896, a mechanical filter was put in operation, through which all the water supplied to the town is passed. Water from the filter-gallery is first pumped to a tank, on entering which it is treated with milk of lime. As the water passes through the tank, it is aerated by means of perforated nozzles in the bottom of the tank, supplied with compressed air. From this aerating tank it passes to the settling tank, receiving in its passage from one tank to the other a solution of aluminum sulphate. In the settling tank a large portion of the iron is precipitated, and the supernatant liquid passes to the filters, which consist of 6 circular tanks, 8 feet 8 inches in diameter and 8 feet deep, partially filled with sand. From the filters water passes to a small storage tank, from which it is pumped to the stand-pipe and supplied to the town. The filters are washed out each day, by reversing the current of water, at the same time agi-

READING.

tating the sand. It will be seen from the tables of analyses which follow that a large proportion of the iron is removed, but that the hardness of the water is greatly increased: -

Chemical Examination of Water from the Filter-gallery of the Reading Water Works.

^{*} Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

Microscopical Examination.

An insignificant number of organisms was found in some of these samples.

Odor, none. On heating, a slight odor was developed in some of the samples.—The samples were collected from the weir over which the filtered water passes on its entrance to the storage tank at the pumping station.

REVERE AND WINTHROP.

WATER SUPPLY OF REVERE AND WINTHROP — REVERE WATER COMPANY.

The advice of the State Board of Health to the Revere Water Company, relative to securing an additional water supply, may be found on pages 37 to 39 of this volume.

The wells of this company, located at Revere, receive a large amount of sea-water, which increases with the increased draft on the wells during the summer and fall, making the water exceptionally hard and giving it a saline taste.

^{*} September.

Note to analyses of 1896: Odor, none. On heating, a faintly earthy odor was developed in the October and December samples.—The samples were collected from faucets in Revere and Saugus, supplied wholly from the Saugus wells.

Microscopical Examination.

An insignificant number of organisms was found in sample No. 16022; no organisms were found in the other samples.

REVERE AND WINTHROP.

Odor of No. 16842, faintly vegetable; of the others, none. — The first sample was collected from a tubular test well in the valley of Crystal Brook, near the corner of Main and Howard streets, Saugus; the second and third, from a tubular test well near the corner of Main Street and the Newburyport turnylke, in Saugus; the fourth, from a tubular test well in rear of fire department building, Broadway, Revere; the last three, from a tubular well near junction of Washington and Fenno streets, Revere. The samples were collected in connection with an investigation for an additional water supply for Revere.

Microscopical Examination.

No organisms.

SALEM AND BEVERLY.

WATER SUPPLY OF SALEM AND BEVERLY.

The character of the water of Wenham Lake has been affected during the years 1895 and 1896 by the mixture with it of water from the Longham Meadow Reservoir, which has a much higher color and contains more organic matter than the water of the lake.

Chemical Examination of Water from Wenhan Lake, in Beverly and Wenham.

Odor of the first sample, none; of the last, vegetable. — The first sample was collected from Smith's Spring, near the junction of two brooks above the road from Sheffield to Hartsville; the second, from Clark's Spring, a short distance north of Smith's Spring.

Microscopical Examination.

An insignificant number of organisms was found in No. 16561; no organisms were found in the other sample.

WATER SUPPLY OF SOMERVILLE.

(See Boston, Mystic Works.)

WATER SUPPLY OF SOUTHBRIDGE - SOUTHBRIDGE WATER SUPPLY COMPANY.

The works of the Southbridge Water Supply Company were enlarged in 1894 by the construction of a reservoir on Hatchet Brook in the southerly part of the town, from which water is supplied to the town by gravity. Much of the soil and vegetable matter is said to have been removed from the area covered with water. The reservoir has a watershed of 3 square miles, which contains a very small population.

Chemical Examination of Water from the Lower Reservoir of the Southbridge Water Works.

Odor, none, becoming faintly mouldy on heating. — The sample was collected from a faucet in Southbridge supplied with water from Glover Spring. This spring is used as a source of supply for several families.

Microscopical Examination.

No organisms.

WATER SUPPLY OF SPRINGFIELD.

Water from the Ludlow Reservoir was used for the supply of the city until July, 1896, at which time the taste and odor of the water became so objectionable that its use was discontinued. Water was pumped from Chapin Pond from July 7 until Sept. 7, 1896. During an investigation by the Board relative to the best method of preventing the occurrence of tastes and odors in the water of Ludlow reservoir, frequent samples of water from various sources in the vicinity were analyzed. The results of the analyses are given in the tables which follow.

Chemical Examination of Water from the Canal which conveys Water from Jabish,

Axe Factory and Broad Brooks to the Receiving Basin of the Springfield Water

Works, at Ludlow.

^{*} Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

Odor, vegetable and frequently mouldy. — The samples were collected from the canal, at its entrance into the receiving basin.

Microscopical Examination of Water from the Canal which conveys Water from Jabish, Axe Factory and Broad Brooks to the Receiving Basin of the Springfield Water Works, at Ludlow.

^{*} These analyses were made by Prof. William R. Nichols, for the city of Springfield, from samples collected about once a week, between July 1, 1876, and Sept. 30, 1877.

Note to analyses of 1896: Odor, decidedly grassy and mouldy, occasionally vegetable and sweetish, rarely unpleasant. On heating, the odor became stronger and decidedly sweet and grassy.— The samples were collected from the reservoir, 2 or 3 feet beneath the surface. For monthly record of height of water, see page 321.

llected about once a week, between July 1, 1876, and Sept. 30, 1877.

† June to December.

‡ January to September.

§ May to December.

 $[\]parallel$ Where more than one sample was collected in a mouth, the mean analysis for that month has been used in making the average.

SPRINGFIELD.

^{*} Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

Odor, frequently none, occasionally vegetable and unpleasant. A fishy odor was observed in the last three samples. — The samples were collected from the pond, near the surface. Water from this source was pumped into the distributing system of the Springfield water works from July 7 until Sept. 7, 1896.

Microscopical Examination of Water from Chapin Pond, Ludlow.

^{*} Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

Odor, generally distinctly mouldy or grassy, occasionally vegetable and unpleasant. — The samples were collected from the reservoir, near the surface. This reservoir is a distributing reservoir of the Springfield Water Works.

Microscopical Examination of Water from Van Horn Reservoir, Springfield.

 $^{^{}st}$ Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

Odor, generally none, occasionally vegetable. On heating, the odor became faintly vegetable or earthy.— The samples were collected from the pond, near the surface. This pond is not used as a source of public water supply.

WATER SUPPLY OF STONEHAM.

(See Wakefield.)

WATER SUPPLY OF SWAMPSCOTT AND NAHANT. — MARBLEHEAD WATER COMPANY.

The water supplied to Swampscott and Nahant during 1896 was drawn from three sources, viz.: a large well and a group of 72 tubular wells in the valley of Stacy's Brook, not far from the seashore; a system of tubular wells in Paradise Road; and a system of tubular wells a short distance east of the Swampscott station on the eastern division of the Boston & Maine Railroad. The wells in the valley of Stacy's Brook are located in densely populated territory, and are probably affected by the presence of a small amount of sea-water.

SWAMPSCOTT AND NAHANT.

The advice of the State Board of Health to the Marblehead Water Company relative to taking an additional water supply from the ground in the neighborhood of Thompson's Meadow in Salem may be found on pages 40 to 42 of this volume.

^{*} June to December.

Note to analyses of 1896: Odor of Nos. 16003 and 16188, faintly earthy; of the others, none. — Nos. 16389, 16544 and 17322 were collected from the large well near the pumping station; Nos. 15852, 16003, 16188, 16780 and 16924, from a faucet at the pumping station; the others, from faucets in the town.

Microscopical Examination.

An insignificant number of organisms was found in sample No. 15852; no organisms were found in the remaining samples.

[†] January to May.

[†] October.

 $[\]S$ Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

Odor of the last sample, faintly earthy, disappearing on heating; of the others, none. — The samples were collected as follows: No. 17104, from a spring near the roadside at southerly end of Thompson's Meadow; No. 17105, from a spring in Thompson's Meadow, about 400 feet north of Peahody Road and 300 feet west of railroad; No. 17106, from a tubular well about 25 feet from the latter spring; No. 17107, from a tubular well about 400 feet north of the Peabody Road and 125 feet from the railroad; the last five samples, from the pump drawing water from a group of 6 tubular wells at the southerly end of Thompson's Meadow, during a pumping test of twelve days' duration. The first sample (17581) was collected on October 3, about an hour after pumping began, and the last sample was collected on the last day of the test.

Microscopical Examination.

An insignificant number of organisms was found in samples Nos. 17104, 17105 and 17107; no organisms were found in the remaining samples.

^{*} June to December.

Note to analyses of 1896: Odor of the first sample, faintly mouldy, becoming distinctly vegetable and grassy on heating; of the second, unpleasant; of the third, none; of the last, faintly fishy and oily, becoming stronger on heating. — The samples were collected from the filter-basin. Water from this source was used during the year 1896 for only two days in the month of April.

WALPOLE.

WATER SUPPLY OF WALPOLE.

Population in 1895, 2,994. The works are owned by the town, and were completed in January, 1896. The source of supply is a system of tubular wells in the valley of Low Brook, about a third of a mile above its junction with the Neponset River in the southerly part of the town. The system consists of 7 two and one-half inch tubular wells and 33 two-inch tubular wells, sunk to depths ranging from 35 to 60 feet. The wells are driven in two parallel lines, at right angles to the brook, one extending from the pumping station to the brook and the other line about 50 feet away, extending across the brook. Water from the wells is pumped directly into the distributing pipes and to two covered iron tanks, one at East Walpole, 25 feet in diameter and 45 feet high, and the other at South Walpole, 20 feet in diameter and 35 feet high. Distributing mains are of cast iron, and service pipes are chiefly of wrought iron, lined with cement.

Odor, none. On heating, a faintly earthy odor was developed in the February and August samples.

— The first two samples were collected from a faucet at the pumping station; the remaining samples, from one of the tubular wells at the pumping station.

Microscopical Examination.

An insignificant number of organisms was found in sample No. 16111; no organisms were found in the remaining samples.

^{*} June to December.

Note to analyses of 1896: Odor of the October sample, faintly mouldy, disappearing on heating; of the others, none.—— The samples collected in August and December were taken from the filter-basin; the other samples, from a faucet at the pumping station.

Microscopical Examination.

An insignificant number of organisms was found in these samples.

[†] January to May.

¹ February.

[§] July to December.

^{*} June to December.

Note to analyses of 1896: Odor, generally none, sometimes vegetable, and occasionally mouldy.

The samples were collected from a faucet at the pumping station.

The color of this water is affected by the presence of iron. For a statement as to the effect of the presence of iron upon the color of a ground water, see page 81.

[†] January to May.

¹ August.

[§] September to December.

WATERTOWN AND BELMONT.

Microscopical Examination of Water from a Faucet in the Pumping Station of the Waterlown Water Supply Company.

^{*} September.

‡ July. § June and October.

|| July and August.

Note to analyses of 1896: Odor, none. On heating, a faintly mouldy odor was developed in the last sample. -- The samples were collected from the well, at Williams Spring.

Microscopical Examination.

An insignificant number of organisms was found in sample No. 17442; no organisms were found in the remaining samples.

Chemical Examination of Water from the Distributing Reservoir of the Wellesley Water Works.

WATER SUPPLY OF WESTON. — WESTON AQUEDUCT COMPANY.

Population in 1895, 1,710. The works are owned by the Weston Aqueduct Company, and water was first introduced in January, 1896. The source of supply is a well situated in the valley of Cherry Brook. The well is 11 feet in diameter and 25 feet deep, built of stone laid without mortar and covered with a wooden roof. Water is forced from the well to the town and to a covered distributing reservoir 50 feet in diameter and 15 feet deep, built of stone and lined with coment. Distributing mains are of cast iron, service pipes are of galvanized iron.

Odor of No. 16878, distinctly unpleasant; of the others, none. On heating, a distinctly fishy odor was developed in No. 17294 and a distinctly earthy odor in No. 17739.— The samples were collected from the reservoir.

Microscopical Examination.

An ineignificant number of organisms was found in these samples.

Odor in April, distinctly earthy; in June, faintly unpleasant; at other times, none. — The samples were collected from the reservoir.

Microscopical Examination.

An insignificant number of organisms was found in these samples.

WINCHENDON.

WATER SUPPLY OF WINCHENDON.

Population in 1895, 4,490. The works are owned by the town, and water was introduced in December, 1896. The source of supply is a covered masonry well $28\frac{1}{2}$ feet in diameter and 25 feet deep, located in Prentiss Meadow, in the valley of Miller's River, about $1\frac{1}{2}$ miles south-east of the village. The supply obtained from the well is supplemented by a line of 12-inch tiled pipe, which has been laid with open joints, extending from the well a distance of about 375 feet, with short branches at frequent intervals, the total length of pipe being about 1,065 feet. This pipe has been laid about 5 feet beneath the surface of the ground. Water is pumped from the well to the town and to a covered masonry reservoir 13,000 feet distant from the pumping station. The distributing reservoir is circular in form, having a diameter of 70 feet and a depth of 19 feet. Service pipes are of wrought iron coated with tar.

* May to December.

Note to analyses of 1896: Odor, generally distinctly vegetable, sometimes unpleasant, frequently becoming grassy or mouldy on heating. In June the odor was decidedly fishy and oily. — The samples were collected from the reservoir, near the dam.

Microscopical Examination of Water from the Middle Reservoir of the Winchester Water Works.

| | | } | | | | | | | | | 1 | | ii | | |

^{*} June to December.

Note to analyses of 1896: Odor, generally faintly vegetable, frequently stronger on heating. The samples were collected from the reservoir at the gate house, I foot beneath the surface.

For record of heights of water in this reservoir, see page 384.

WATER SUPPLY OF WRENTHAM.

The advice of the State Board of Health to Lincoln, Bacon & Co. with reference to the protection of the purity of Bacon's Pond in the village of Plainville in that town, from which water is drawn for the supply of several families in the village, may be found on page 77 of this volume. Samples of water collected from the pond and from a spring from which a portion of the water supply is taken are given in the following tables:—

Chemical Examination of Water from Spring in Wrentham. [Parts per 100,000.]

Odor of the first sample, faintly vegetable, becoming distinctly vegetable and mouldy on heating; of the last, distinctly vegetable and mouldy.— The first sample was collected from a tap on the pump while pumping from the pond; the other, from the pond opposite the ice-house, near shore.

Microscopical Examination.

An insignificant number of organisms was found in these samples.

EXAMINATION OF RIVERS.

EXAMINATION OF RIVERS.

During the year 1896 regular monthly examinations were made of the waters of the Blackstone, Hoosac, Housatonic, Merrimack, Nashua, Neponset, Saugus and Ware rivers, and occasional examination of other rivers in the State. Nearly all of the results of these examinations will be found arranged alphabetically by rivers in the pages which follow, but some of them are given on preceding pages, in connection with the examinations of water supplies, under the names of the towns where the samples were collected, as follows:—

| | | | | | PAGE |
|------------------------|--|--|--|--|------|
| Merrimack at Lawrence, | | | | | 190 |
| Merrimack at Lowell, | | | | | 204 |
| Neponset at Hyde Park, | | | | | 182 |
| Saugus at Saugus, . | | | | | 216 |

BLACKSTONE RIVER.

The regular monthly examinations of the waters of the Blackstone River have been continued as in previous years, and the results are given in the tables which follow.

During the year ending Nov. 30, 1896, an average of 16,000,000 gallons per day of mingled sewage and brook water taken from the Mill Brook Channel were treated at the Worcester Precipitation Works, and about 3,500 tons of quicklime were used, making the amount of lime used per million gallons of sewage treated, 1,212 pounds. The effluent from the precipitation works and excess of flow of Mill Brook over the amount treated was discharged into the Blackstone River.

The first of the following tables is taken from the report of the superintendent of sewers of the city of Worcester for the year ending Nov. 30, 1896, and contains the monthly averages of analyses of samples of sewage and effluent collected at the Worcester Precipitation Works, and the percentage of matters removed from the sewage by treatment at these works.

WORCESTER SEWAGE PURIFICATION WORKS.

Abstract of Analyses of Sewage and Effluent.

[Taken from the annual report of the superintendent of sewers of the city of Worcester for the year ending Nov. 30, 1896.]

Note. — Monthly averages are made from dally analyses of sewage and effluent. The daily sewage samples consist of forty-eight portions taken half hourly. Sewage samples are taken as nearly as possible in proportion to the amount of sewage being received at the time of sampling. Effluent samples consist of twenty-four portions taken hourly.

^{*} March to December.

Note to analyses of 1896: Odor, musty. - The samples were collected from the river.

MERRIMACK RIVER.

The usual monthly examinations of the water of this river opposite the intakes of the Lowell and the Lawrence Water Works have been continued during 1896, the detailed results of which may be found on pages 204 and 190 of this volume. A comparison of the analyses made at these two places during the year is given in the following table:—

MERRIMACK RIVER.

Table comparing the Analyses above Lowell with those above Lawrence, 1896.

[Parts per 100,000.]

| | | EVAL | OUE ON PORA- ON. | | Амм | IONIA. | | | NITE | | |
|---------------------------------------|--------|--------|------------------------|-------|--------|--------------|-----------------|-----------|-----------|-----------|-----------|

In order to compare these results with similar ones obtained in previous years, another table is presented, which shows the increase in impurities as the water passes from a point above Lowell to Lawrence, as given in the last line of the above table, and the corresponding increase in previous years:—

Increase in the Amount of Impurities in the Merrimack River Water, from a Point above Lowell to Lawrence, as determined by the Regular Monthly Examinations of Different Years.

^{*} August, November and December.

Note to analyses of 1896: Odor, distinctly vegetable and mouldy. — The samples were collected from the river, at the railroad bridge, near Cold Brook station, in the south-easterly part of the town of Barre.

SUMMARY

OF

WATER SUPPLY STATISTICS;

ALSO

RECORDS OF RAINFALL AND FLOW OF STREAMS.

SUMMARY OF WATER SUPPLY STATISTICS.

During the year 1896 a public water supply was introduced for the first time into the towns of Hatfield, Rutland, Walpole, Weston and Winchendon, and a new supply was introduced into the town of Bradford to replace the former supply which had become objectionable, owing to the presence of an excessive amount of iron in the water. The following table gives a classification by population of cities and towns having and not having public water supplies Dec. 31, 1896. The populations are taken from the census of 1895:—

| | Popt (18 | LATIO 895). | | | Number of Places of Given Population having a Pub- lic Water Supply. | Total Population of Places in Preceding Column. | Number of Places of Given Population not having a Public Water Supply. | Total Population of Places in Preceding Column. |
|----------------|----------|-------------|----|---|---|---|---|---|
| Under 500, . | ٠ | | | | 0 | 0 | 36 | 13,287 |
| 500-1,000, . | | | | | 4 | 3,301 | 55 | 42,503 |
| 1,000-1,500, . | | | | | 10 | 11,912 | 37 | 45,331 |
| 1,500-2,000, . | | | | | 8 | 13,825 | 31 | 53,651 |
| 2,000-2,500, . | | | ٠. | | 9 | 19,990 | 14 | 31,074 |
| 2,500-3,000, . | | | | | 7 | 19,867 | 11 | 29,624 |
| 3,000-3,500, . | | | | | 10 | 32,515 | 7 | 22,599 |
| 3,500-4,000, . | | | | | 5 | 18,219 | 1 | 3,569 |
| 4,000-4,500, . | | | | | 9 | 39,006 | 1 | 4,055 |
| Above 4,500, . | | | | ٠ | 97 | 2,089,816 | 1 | 6,639 |
| TOTALS, . | | | | | 159 | 2,248,451 | 194 | 251,732 |

From the totals given in the preceding table it will be seen that of the 353 cities and towns in the State, 159, or 45 per cent., have a public water supply, and the total population of the places supplied represents 89.93 per cent. of the total population of the State. The number of people to whom a public water supply is available is somewhat less than the total population of the municipalities supplied, but the difference is not large. There are now 10 towns

having, by the census of 1895, populations exceeding 3,000 which are not provided with a public water supply. These are given in the following table:—

| 3 | ow. | ns. | | Population in 1895. | | Tow | NS. | | Population in 1895. |
|---------------|-----|-----|--|---------------------|--------------|-----|-----|---|---------------------|
| Blackstone, | | | | 6,039 | Pepperell, . | | | | 3,321 |
| Barnstable, | | | | 4,055 | Dudley, . | | | | 3,203 |
| North Andover | , | | | 3,569 | Chelmsford, | | | | 3,162 |
| Sutton, . | | | | 3,420 | Dartmouth, | | | ٠ | 3,107 |
| Tewksbury, | | | | 3,379 | Deerfield, . | | | | 3,007 |

In the following table the various water supplies are classified according to the dates when a fairly complete system was first introduced into a city or town:—

| YEARS. | | | | Number of Places supplied. | | | | YEA | RS. | | Number of Places supplied. |

There has been no change in the ownership of any of the works during the past year. All of the 32 cities in the State having an aggregate population of 1,635,767 own their water works. Of the 127 towns having a public water supply, 81, with a total population of 398,395, own their works, while 47, having a total population of 214,289, are supplied by private companies. The total population in both cities and towns owning works is 2,034,162, against 214,289 in those supplied by private companies. The following table gives statistics with regard to the consumption of water in cities and towns of this State, where such records are kept. The consumption per inhabitant has been obtained by dividing the average daily consumption by the total population of the city in 1896, and, consequently,

is somewhat less than the amount used per consumer, because there are in all cities and towns some who do not use the public water supply. This difference is most marked in towns containing villages to which the public water supply has not been extended, and in towns where the works have been in operation but a short time and where water has not come into general use. In some towns the population during the summer months is much greater than is shown by census returns, and in such cases the consumption per inhabitant as given in the table is somewhat higher than it would be if allowance was made for the increased population in summer.

RAINFALL.

The rainfall for the year 1896 was 3.9 inches less than the normal, as shown by an average of the recorded rainfall at several stations in various parts of the State covering periods of many years. There was an excess of rainfall only in the months of February, March and September, the greatest excess being in September. The deficiency in rainfall was distributed throughout the remaining months, the greatest deficiency occurring in January, April, May, August, November and December. The distribution of rainfall was such as to cause a low flow in the streams in August, but the large rainfall in September caused the flow in the streams during the months of September and October to be above the normal. In the following table is given the normal rainfall in each month in 1896, and the departures from the normal:*—

| | Normal Rainfall Inches. | Rainfall, 1896. Inches. | Excess or Deficiency. | | Normal Rainfall. | Rainfall, 1896. Inches. | Excess or Deficiency Inches. |
|---------------------|-------------------------------|-------------------------------|-----------------------|------------------|---------------------|-------------------------------|------------------------------------|
| 1896. January, . | 3.88 | 1.97 | -1.91 | 1896. August, | 4.31 | 2.63 | -1.68 |
| February, . | 3.67 | 4.85 | +1.18 | September, . | 3.37 | 6.67 | +3.30 |
| March, | 4.00 | 5.90 | +1.90 | October, | 4.09 | 3.60 | -0.49 |
| Aprll, | . 3.31 | 1.41 | -1.90 | November, | 4.03 | 2.99 | -1.04 |
| May, | 3.66 | 2.54 | -1.12 | December, | 3.56 | 1.76 | -1.80 |
| June, | 3.25 | 2.96 | -0.29 | Tomar | 15.00 | 41.10 | 2.00 |
| July, | 3.87 | 3.82 | -0.05 | Total, | 45.00 | 41.10 | -3.90 |

To enable the conditions preceding the collection of samples of water in any portion of the State to be understood, the following tables are presented, which give the daily rainfall in inches at nine stations scattered throughout the State:—

^{*} This and subsequent tables of rainfall have been prepared from the records of the New England Weather Service.

Daily Rainfall in Inches at Nine Places in Massachusetts, Geographically selected.

FLOW OF STREAMS.

The records of the flow of the Sudbury River for 1896 indicate that the flow of the streams of the State was slightly less than the average for the past twenty-two years. In order to show the relation between the flow of the Sudbury River during each month of 1896 and the normal flow of the same river, as deduced from observations covering a period of twenty-two years, from 1875 to 1896 inclusive, the following table has been prepared. The area of the watershed of the Sudbury River above the point where its flow was measured is 75.2 square miles.

Table showing Average Monthly Flow of Sudbury River for the Year 1896, in Cubic Feet per Second per Square Mile of Drainage Area, also Departures from the Normal Flow.

| | | M | ГИO | н. | | | NORMAL FLOW. Cubic Feet per Second per Square Mile. | ACTUAL FLOW IN 1896. Cubic Feet per Second per Square Mile. | EXCESS OR DE- FICIENCY. Cubic Feet per Second per Square Mile. |

The next table shows the weekly fluctuations during 1896 in the flow of the two streams most carefully measured, namely, the Sudbury and the Merrimack. The flow of these streams, particularly the Sudbury, will serve to indicate the condition of the other streams in eastern Massachusetts.

| WEEK ENDING SUNDAY. 1896. | SUDBURY RIVER. Cubic Feet per Second per Square Mile. | MERRIMACK RIVER. Cubic Feet per Second per Square Mile. | WEEK ENDING SUNDAY. 1896. | SUDBURY RIVER. Cubic Feet per Second per Square Mile. | MERRIMACK RIVER. Cubic Feet per Second per Square Mile. |

In the annual report of the State Board of Health for the year 1890, pages 338 to 340, a table taken from the annual reports of the Boston Water Board was printed, giving the records of rainfall upon the Sudbury watershed, and its total yield expressed in inches in depth on the watershed (inches of rainfall collected) for the sixteen years from 1875 to 1890 inclusive. The corresponding records for the years 1891 to 1895 inclusive were given in the annual report in 1895, page 430. In the following table is given the record for 1896, together with the average of the records for the whole twenty-two years:—

Rainfall received and collected on the Sudbury River Watershed.

The Sudbury River records are particularly valuable as a basis for estimating the yield of other watersheds in Massachusetts, both on account of the accuracy with which the measurements have been made, and the absence of abnormal conditions which would unfavorably affect the results. It is, therefore, thought advisable to publish in the following table those portions of the records relating to the yield of this watershed for each of the twenty-two years, and in doing so the flow from the watershed is expressed in gallons per day per square mile instead of inches, and the depth of rainfall collected, in order to render the table more convenient for use in estimating the probable yield of other watersheds.

Yield of the Sudbury River Watershed in Gallons per Day per Square Mile.*

^{*} The area of the Sudbury River watershed used in making up these records included water surfaces amounting to about 1 per cent. of the whole area, from 1875 to 1878 inclusive, and subsequently increasing by the construction of storage reservoirs to about 3 per cent. in 1886. The watershed also contains extensive areas of swampy land, which, though covered with water at times, are not included in the above percentages of water surfaces.

EXPERIMENTS

UPON THE

PURIFICATION OF SEWAGE AND WATER

AT THE

LAWRENCE EXPERIMENT STATION,

DURING THE YEAR 1896.

[425]

EXPERIMENTS UPON THE PURIFICATION OF SEWAGE AND WATER AT THE LAWRENCE EXPERIMENT STATION.*

By HARRY W. CLARK, Chemist in Charge.

The year 1896 is the ninth that the investigations of the Lawrence Experiment Station have been continued. The work has been carried on under the general supervision of Hiram F. Mills, A.M., C.E., a member of the State Board of Health, with the writer in direct charge. Mr. W. R. Copeland is in charge of the biological department and Mr. F. B. Forbes is assistant chemist. Mr. E. F. Badger and Mr. S. De M. Gage are assistants in the chemical and biological departments respectively. Dr. Thomas M. Drown is consulting chemist.

SEWAGE PURIFICATION.

The investigations upon the subjects of sewage and water purification have, during 1896, added much valuable data to the store of information which the Board has been accumulating during the past nine years.

The principal sewage filters which were constructed at the beginning of these investigations have been in operation during the past year. The continued systematic analyses of the applied sewage and effluents, occasional analyses of the filtering materials themselves, and the various observations in regard to their method of operation add continually to our knowledge of the permanency of sewage filters of different materials, and of the best means to maintain this permanency under different conditions. A number of new experiments have been begun for the purpose of gaining information upon subjects of increasing importance in sewage disposal, including the proper and economical disposition of the waste liquors or sewage

^{*} A full account of the work done at the Lawrence Experiment Station for the years 1888 and 1889 is contained in a special report of the State Board of Health upon the Purification of Sewage and Water, 1890. A similar account for the years 1890 and 1891 is contained in the twenty-third annual report of the Board for the year 1891. Since 1891 the results have been published yearly in the annual reports.

from those manufacturing industries in the State which pollute or threaten to pollute our rivers and ponds.

In connection with the study of permanency, investigations of different methods of separating the sludge of the sewage from the main body of the liquid, and thus disposing of the clogging matters which tend to shorten the life of sewage filters, have been continued.

Methods for hastening and increasing the purifying action of filters by different means of increasing the air supply are of considerable scientific and practical interest, and experiments on these subjects have been continued throughout the year.

In addition to the chemical and mechanical examinations of filtering materials in use at the station, a large number of soils and sands from the following places have been examined during the year, either in connection with applications made to the Board for advice with reference to sewerage systems and water supplies or in connection with the Neponset River investigation: Norwood, East Walpole, Canton, Taunton, Provincetown, Danvers Lunatic Hospital, Rutland, Stockbridge and Leicester.

PURIFICATION OF MANUFACTURING SEWAGE.

Various industries produce a large volume of waste liquor or sewage. It can be stated that the volume of sewage turned out daily by one manufacturing plant is often as great as the sewage of a village of considerable population, and the organic matters contained in manufacturing sewage are often much greater than in the same volume of town sewage.

These excessive amounts of organic matters, together with various chemicals used in the manufacturing processes and also present in the sewage, often render the problem of successful and economical disposal of this sewage exceedingly difficult.

During the past year the composition and disposal of the sewage of two tanneries, engaged in different lines of work, three paper mills and two wool-scouring establishments have been studied.

TANNERY No. 1.

This tannery is engaged in preparing and tanning calf skins. Of these skins large numbers are imported, and, to prevent decomposition en route, come packed in sulpho naphthol, a germicide, and this has been present in the sewage throughout the period of examination.

To aid in the process of freeing the skins of hair, a ton or more of sulphide of arsenic is used each month, mixed with lime to form a soluble salt of arsenic, and as a result of this the sewage always contains arsenic in suspension and solution. Various other chemicals and dyes are used in the tannery and are present in the sewage.

The sewage as it flows from the tannery is a heavy, thick and offensive liquid, containing a very large amount of organic matter and generally colored by the dyestuffs present in it. A large amount of the organic matter present is in suspension, and experiments have shown that it will settle out from the main body of the sewage very completely in one hour, this rapid sedimentation being aided by the lime and other chemicals in the sewage.

There is generally enough arsenic in this sewage to prevent or almost prevent the growth of bacteria, and hence if it were applied directly to filtration areas the bacterial actions, which cause the purification of sewage and upon which the life and value of a sewage filter depend, could not take place. A considerable proportion of the arsenic is held by the sludge, or organic matter in suspension, and is carried downward with it when the sewage is allowed to stand and settle. The supernatant sewage, after this sedimentation, contains, however, generally enough arsenic to check bacterial action, and if applied to filtration areas there would probably be an accumulation of arsenic in the filter in the course of time in sufficient quantity to permanently check nitrification.

The volume of sewage flowing from the tannery generally exceeds 200,000 gallons daily, and its character is shown by the following monthly averages of the chemical analyses of a large number of samples.

In regard to the bacteria in this sewage the numbers given in this table are of those present in the supernatant sewage, samples for planting being taken without shaking the bottle. The reason of this way of recording the numbers present is that if the bottle were shaken, and the sample planted contained its proportionate amount of the sludge, this sludge generally contained enough arsenic to sterilize the plate and prevent bacterial growth. This was particularly true of the samples collected during the last six months of the year.

Removal of Arsenic by Coke or Iron.

Methods for removing this arsenic have been studied, and we have found that by passing the sewage through a filter or strainer of coke breeze it is quite completely freed from the arsenic. This removal is probably due to a combination of the arsenic with the iron in the coke and the formation of an insoluble double salt of iron and arsenic which is retained in the coke. The same result is accomplished by passing the sewage through iron filings or turnings.

These methods of removing arsenic are important and can undoubtedly be applied in the case of other arsenic-bearing manufacturing sewages.

Average Amount of Arsenic ($AS_2 O_3$) in Entire and Supernatant Sewage and Effluent of the Coke Strainer.

| | [Par | ts per | 100,00 | 00.] | | | |
|-------------------------------|------|--------|--------|------|--|--|--------|
| In entire tannery sewage, | | | | | | | 8.5447 |
| In supernatant tannery sewa | ge, | | | | | | 1.6757 |
| In effluent of coke strainer. | | | | | | | .0823 |

Much of the effluent of the coke strainer contained no arsenic, but occasionally, when an excessive amount was applied and the strainer was overworked, some would pass through.

Examination of the coke proved that a large percentage of the arsenic was retained in the upper few inches of the strainer. Thus, for example, a small filter containing 2 feet in depth of coke breeze was put in operation October 1 and flooded each day for two weeks with this sewage. The effluent was examined each day and contained no arsenic, and on October 15 the coke itself was examined with the following result:—

Arsenic ($AS_2 O_3$).

[Parts per 100,000.]

| In upper 4 inches of coke, | | | • | | 36.40 |
|-----------------------------|--|--|---|--|-------|
| In middle 4 inches of coke, | | | | | 6.60 |
| In lower 4 inches of coke, | | | | | .20 |

Filtration of the Sewage of Tannery No. 1.

Two sand filters and the coke strainer before mentioned have been operated, receiving the supernatant sewage, and are designated as filters Nos. 71, 72 and 73.

Filter No. 71.

This filter contains 4.5 feet of sand of an effective size of 0.23 millimeter and has received the supernatant sewage at the rate of 50,000 gallons per acre daily. It has produced a satisfactory effluent generally, but nitrification has been entirely destroyed in it at those periods when the applied sewage has contained rather more arsenic than usual, as during September and again during December, as shown by the table beyond. In warm summer weather nitrification is quickly re-established in a filter, but if it ceases in winter it does not start again until warmer weather returns, thus causing poor purification and excessive storage of organic matter in a filter during the cold weather.

Filter No. 72.

This filter contains 2 feet in depth of coke breeze and has received the supernatant sewage at the rate of 100,000 gallons per acre daily. This rate kept the surface of the coke flooded for about two hours daily and could have been increased and still resulted in the removal of the arsenic. It has removed considerable organic matter and generally all the arsenic from the sewage. The object of this filter has been to free the sewage of germicides and thus get it into such a condition that the organic matter can be attacked by the bacteria of

decomposition, putrefaction and nitrification. That this result is accomplished is shown by the tables beyond, for when the sewage applied to this coke strainer or filter has contained so much arsenic that only a few hundred bacteria per cubic centimeter were found growing in it, its effluent has contained several million per cubic centimeter.

Filter No. 73.

This filter, containing 4.5 feet of sand of an effective size of 0.23 millimeter, has received the effluent of Filter No. 72 at the rate of 100,000 gallons per acre daily, and has maintained uniformly good nitrification and purification.

The following tables give the monthly averages of the analyses of the effluents of these three filters:—

Effluent of Filter No. 71.

TANNERY No. 2.

Studies in regard to composition and methods of disposal of the sewage of a tannery engaged in preparing and tanning sheep skins were begun during the latter part of 1895 and have been continued during 1896. The sewage of this tannery varies in daily volume

[†] One analysis made in December.

from 20,000 to 50,000 gallons, and is a heavy liquid varying in color from time to time and having an exceedingly offensive odor. It seldom contains any substance of a character to check bacterial action, and the large amount of organic matter present is in an advanced state of decomposition and hence readily attacked by the bacteria in a filter. The sludge is at times great in volume as compared with the sludge of ordinary town sewage and very rich in fats and nitrogenous matters.

The following table gives the monthly averages of the chemical analyses of the sewage of this tannery:—

Sewage of Tannery No. 2.

A filter to which this sewage has been applied was in operation from September, 1895, until November, 1896. The filter contained 26 inches in depth of sand, of an effective size of 0.14 millimeter, over gravel underdrains, and during the first few weeks of its operation nitrification was active and its effluent of an entirely satisfactory character. It was being operated at this time at a rate of about 120,000 gallons per acre daily. After a short period, however, it

became badly clogged, owing to the large amount of sludge in the applied sewage and its accumulation upon the surface of the filter.

This sludge was of a gelatinous character when wet, and excluded the necessary air from the pores of the filter; when dry it was, as might be expected, of a leathery nature and would crack and separate into small pieces, and when removed would crumble into a powdery mass and remain in this condition, producing no offensive odor.

It is probable that, with a continual removal of this dry sludge from the filter's surface, good nitrification would have continued, although the depth of sand in the filter was not sufficient to obtain the best results. The filter has been operated during 1896 at an approximate rate of 25,000 gallons per acre daily, and has removed a large percentage of the organic matter from the sewage, but nitrification has not been active.

The following table gives the monthly averages of the analyses of the effluent of this filter:—

Effluent of Large Filter.

In January a filter was started to receive this supernatant sewage. This filter contains 4 feet in depth of sand of an effective size of 0.14 millimeter, and is located in a building where the temperature is only slightly above the freezing point during the winter. As a result of this low temperature nitrification did not begin to be active until the

approach of warm weather. Sewage was applied for four months at the rate of 120,000 gallons per acre daily, but this rate was excessive for so strong a sewage and was reduced to 60,000 and then to 30,000 gallons per acre daily. Since the first of May nitrification has been exceedingly active and the effluent of the filter clear and practically odorless.

The following table gives the average analyses of the effluent, and a study of this table will show that much of the nitrogen stored in the filter during the pre-nitrification period has passed away in the effluent since the period of active nitrification began:—

Effluent of Filter receiving Supernatant Tannery Sewage.

Filter No. 75.

In order to prove decisively whether or not the sludge of this sewage really contained a substance which was prejudicial to nitrification, or whether the poor nitrification in the filter receiving the entire tannery sewage was due simply to the amount of sludge applied to it, a third filter was started, to receive a mixture of this sewage and ordinary city sewage. The filter contains 4.5 feet of

sand of an effective size of 0.23 millimeter and has been in operation since June 9.

It received during its first six weeks of operation equal quantities of the two sewages at a total rate of 50,000 gallons per acre daily. The amount of sludge was so great, however, that the surface of the filter became clogged, and the sewage applied was changed so that it contained one part of tannery sewage to two and one-half parts of Lawrence sewage.

Following this change nitrification became, and has continued to be, active and the effluent of the filter has been clear and odorless, thus showing that sewage, such as produced by this tannery, can be mixed with ordinary town or city sewage and successfully purified upon a common filtration area.

The following table gives the monthly averages of the analyses of the effluent of this filter: -

Effluent of Filter No. 75. [Parts per 100,000.]

Conclusions.

The results already obtained by these investigations into the character of tannery sewage and the possibility of disposing of it and destroying its offensive constituents upon the same general principles by which ordinary town sewage is purified are important, and furnish a basis for the study of the disposal of the sewage of tanneries producing waste liquors of a still different nature.

It seems probable that few tanneries produce a sewage more difficult to handle than that of Tannery No. 1, and in cases of this nature, where chemicals inimical to bacterial life are in the liquors, economical methods of removing them can probably be found.

WASTE LIQUORS FROM PAPER MILLS.

The studies in regard to the character and disposal of waste liquors from paper mills have been continued.

These liquors can be divided into two classes, namely, those produced in washing and preparing the stock and those produced in making this stock into paper. Both liquors contain a large amount of organic matter, but the nitrogenous organic matter, principally the dirt washed from the stock, is most abundant in the first. The organic matter in the second liquor is largely of a carbonaceous nature, being the fine pulp which passes through the paper machine. A large amount of various kinds of chemicals is used in cleaning and bleaching the stock and often a large amount of dyestuffs in working the stock up into colored paper. In many mills, also, a clear almost colorless water is needed, and filters for clarifying the water by means of alum as a coagulant are used, and when these filters are cleaned the hydrate of alumina and dirt gathered in the filter are washed into the drain pipes of the mill.

Thus the waste liquors contain both dirt, fibre and chemicals, and a paper mill of ordinary capacity will turn several tons of solid matter into its waste pipes each day.

A large percentage of this waste is of such a character that it will gather in masses, but a large percentage is also in solution, and the volume of waste liquor is very great, that of the mills from which most of our samples for analysis have been taken varying from 2,000,000 to 3,000,000 gallons daily. This great volume, together with the character imparted to it by the chemicals present, makes the problem of satisfactory treatment difficult.

The three following tables present the average analyses of a large number of samples taken from the three waste pipes of paper mill No. 1. In regard to these analyses it can be stated here that at times, when the alum filters are being washed or when the rotary boilers are being emptied, the water running to waste is much more polluted than shown by any of the averages presented.

PAPER MILL No. 2.

The waste pipes of paper mill No. 2 all empty into a raceway underneath the mill. A large number of samples have been taken from this raceway, but their analyses do not accurately represent the waste liquor of the mill, owing to the fact that a large amount of water other than that used in the processes of manufacture in the mill comes into the raceway.

Other tables are given, however, presenting the average analyses of samples taken directly from the waste pipes.

This last table represents the liquor of the previous table after having passed through a screening apparatus in use at this mill. This apparatus is used to save as much of the pulp that has passed through the paper machine as possible, and, as shown by the table, 55 per cent. of the organic matter represented by the albuminoid ammonia and 64 per cent. as represented by the oxygen consumed is screened out by this "save all."

Filter No. 77.

A mixture of these paper mill liquors has been applied to a small filter at the station. This filter contains 4.5 feet of sand of an effective size of 0.23 millimeter and was put in operation during June. The liquor is applied at the rate of 200,000 gallons per acre daily, and a bright, clear effluent, containing very little organic matter, has been obtained; but this purification is apparently caused by the straining out and retention in the filter of the organic matter applied. Some of the organic matter removed from the sewage has undoubtedly passed into the air in gaseous forms of carbon and nitrogen, but nitrification did not become active, although the experiment was carried on during the warmest months of the year, owing, probably, to the various chemicals in the applied liquor. is possible that a larger percentage of the applied nitrogen passes into the air than is the rule with sand filters receiving ordinary town sewage, and that a filter receiving this liquor could be operated indefinitely. It is certainly true that a large percentage of the carbonaceous organic matter is strained out and left upon or very near the surface of the filter and can be removed without removing much of the filtering material. In order to keep a filter in successful operation this would probably have to be removed from time to time or thoroughly broken up at intervals, as it decomposes very slowly.

Effluent of Filter No. 77.

Coke Strainer for Paper Liquor.

As has been mentioned previously, the volume of waste liquors turned out by the paper mills is very large, and as their pollutions are not offensive in the same manner and degree with town sewage, a partial purification which will remove a large percentage of the polluting matters, especially those in suspension, may be in many cases sufficient.

The use of coke as a filtering or straining medium through which to pass sewage at a high rate for the purpose of removing the matters in suspension has been investigated at the station. Its advantages are many, among which is that of removing the surface layer of coke and burning it when it becomes clogged by the sludge removed from the sewage.

In order to test the value of coke in treating these paper liquors a small coke strainer was started at the station, to which they were applied at the rate of 1,000,000 gallons per acre daily. The effluent of this strainer has been very satisfactory, as shown by the following table.

During December the strongly alkaline and highly polluted liquor from the rotary boilers (see page 442) was applied to this strainer.

Screening, Sedimentation and Chemical Precipitation.

A considerable proportion of the organic pollution of these liquors is, as has been said before, in suspension, and is quite readily removed by passing the liquid through wire screens. In some mills a considerable part of the fine pulp which passes through the paper machines is saved in this way, and it is evident that a large portion of

the dirt contained in the wash waters could be screened out in the same manner. If this were done it is evident that the resulting liquor could be applied to a coke strainer at two or three times as great a rate as would be feasible without this straining.

Results upon sedimentation are that about 30 per cent. of the total organic pollutions are removed from these liquors when they are allowed to stand and settle for one hour, and that a period of sedimentation two or three times as long improves this result little if any. This proportion of removal can be increased to about 45 per cent., if either ferrous or aluminum sulphate is added in proportion of 500 pounds per 1,000,000 gallons of liquor treated.

WASTE LIQUORS FROM RINSING AND SCOURING WOOL.

The liquor resulting from scouring and rinsing wool is large in volume, exceedingly rich in organic and mineral matters in suspension and solution, and is of a character not readily acted upon by the agents of decomposition, putrefaction and nitrification.

The liquor of two wool-scouring works has been analyzed frequently during the year and studies and investigations made of methods for their disposal. From one of these plants samples of the scouring liquor itself, and from the other, samples of the entire mixed scouring and rinsing liquor, have been obtained for analysis and investigation.

Beginning in September, 1895, the waste scouring liquor was applied to a sand filter, but the excessive quantity of dirt and fats of various kinds in the liquor caused such a clogging of the surface of the filter that it was soon evident the clogging matters must be removed in some other way than by filtration. Consequently the percentage of removal of these fats and dirts by means of different chemicals has been investigated, and it has been found that the addition of calcium chloride to the liquor causes the formation of a lime soap, and that the fats and dirt in suspension, together with some of the matters in solution, are precipitated. The ordinary precipitants, such as lime and ferrous and aluminum sulphate, have little or no effect upon the liquor. The supernatant liquor, after removing fats, etc., by calcium chloride, is a clear, yellow liquid, containing very little matter in suspension. Its odor is slight and not at all offensive, and it does not change its character on standing. It contains a large amount of organic matter in solution, but, judging from the experiments thus far made, the indications are that it might be

allowed to enter a body of water not used as a water supply without creating a nuisance, as the decomposition of its organic matter would be very gradual.

The following table gives the average monthly analyses of the liquor after its treatment with calcium chloride:—

Experiments upon the feasibility of further purification of this liquor have been carried on and it has been applied to sand and coke filters, and although its clogging properties have been removed by its preliminary treatment so that it passes through the sand or coke at reasonable rates of filtration its character is improved but little. (See page 503, report of 1895.) When applied to a filter in a state of active nitrification it quickly checks and destroys this action, owing, probably, to its degree of alkalinity.

Beginning May 11, this clarified liquor was neutralized and applied to a filter containing 4.5 feet of sand of an effective size of 0.23 millimeter. The rate of filtration was at first 100,000 gallons per acre daily; on August 15 it was reduced to 25,000 and on September 11 to 12,500 gallons per acre daily. At either of these rates the applied liquor was easily disposed of but passed through the filter without material change, as shown by the following table of analyses of the effluent from this filter. The numbers of bacteria in both the applied liquor and effluent have varied from several hundred thousand to several million.

This filter went out of operation at the beginning of November.

Filter No. 76.

Experiments in regard to the ability of the clarified liquor to nitrify when neutralized and mixed with Lawrence sewage have been made. During June a filter containing 4.5 feet of sand of an effective size of 0.23 millimeter was put in operation, receiving equal volumes of the liquor and sewage at a total rate of 100,000 gallons per acre daily. This proportion and rate were continued until August 10, when, as nitrification had not started, the rate was reduced to 50,000 gallons per acre daily and the proportion changed so that the dose applied to the filter contained three parts Lawrence sewage to one part clarified and neutralized wool liquor. This change did not result in allowing nitrification to become established, and on September 11 the proportion was made one to five. Following this change, nitrification, in excess of that which could be accounted for by the change of the organic matter of the Lawrence sewage alone, has taken place and the effluent of the filter has been clear and almost odorless.

The following table gives the average monthly analyses of the dose applied during the period of nitrification, and the second table beyond presents the average monthly analyses of the effluent of the filter:—

WOOL-SCOURING PLANT No. 2.

The waste wool liquor previously described was that resulting simply from the scouring process. This waste scouring liquor is small in volume when compared with the entire waste liquor turned out by a wool-scouring plant, as the volume of water used in rinsing and washing the wool after it is scoured is many times as great as the volume used in the scouring process, — approximately 100 to 1, — and this entire waste liquor contains, of course, much less organic matter, volume for volume, than the scouring liquor alone.

Samples of this entire mixed scouring and rinsing liquor have been collected from the waste drain of a second wool-washing plant and analyzed.

The following table gives an average of these analyses: -

Waste Liquor of Wool-scouring Plant No. 2.

Filter No. 70.

Beginning in June this liquor was applied to a filter containing 4.5 feet of sand of an effective size of 0.23 millimeter, at a rate of 100,000 gallons per acre daily. This rate of filtration continued until September 14, and while the applied dose was readily disposed of by the filter, and its effluent quite clear and generally odorless, nitrification did not become established. On September 14 the dose was so changed that it consisted of 5 parts wool liquor and 1 part Lawrence sewage, and the rate of application was made 120,000 gallons per acre daily. Following this change nitrification became and has remained active.

The following table presents the average monthly analyses of the effluent:—

SOLID MATTERS IN MANUFACTURING WASTES.

The solid matters in the manufacturing sewages studied are large in amount. In the sewage from the calf-skin tannery the average amount of solids present in parts per 100,000 has been 932. As this tannery turns out from 200,000 to 300,000 gallons of sewage daily, it must contain at least 10 tons of solid matter daily. The solids in the sewage from the sheep-skin tannery are about the same, and, calling the average daily flow of sewage at this tannery 35,000 gallons, at least 1 ton of solid matter daily is carried away in the sewage. The solids in the wool-scouring liquor average 4,486 parts in 100,000. The average solids in the paper-mill waste liquors are 40 parts in 100,000, and, calling the average volume of the waste liquors 2,500,000 gallons daily, it appears that at least 4 tons of solid matter are contained in the daily flow.

FATS IN MANUFACTURING SEWAGES.

The tannery sewages and wool liquors are exceedingly rich in fatty matters. At some tanneries the fats pressed from the skins are saved, rendered and used as a dressing for the finished leather. The fats in the wool-scouring liquor consist of the soap used in the process and the animal fats removed from the wool. These fatty matters are almost universally wasted in this country, flowing away in the exhausted scouring liquor, but abroad they are very generally recovered and placed upon the market under the name of "degras." This fat is extensively used, especially in the leather industries, and a large amount is imported by this country. Whether its production in this country would be profitable or not cannot of course be stated here, but it seems probable that wherever the purification of the waste liquor became necessary, the recovery of these fats could be accomplished and their sale pay in part, at least, the cost of purification.

In the table given beyond the figures presented are the averages of many determinations of the fatty matters present in the tannery and wool-scouring liquors investigated.

Bacteriology of Manufacturing Sewages and of the Effluents from Filters Nos. 71 to 76.

From Aug. 15 to Dec. 15, 1896, frequent bacteriological examinations of the manufacturing sewages and the effluents from filters Nos. 71 to 76 were made, in order to determine what species of bacteria they contained, the number of bacteria present per cubic centimeter, and to determine also whether the bacteria contained in these liquors increased or diminished in number when the sewages or effluents were allowed to stand for a few days.

Aug. 15 to Dec. 15, 1896.

The sewage applied to filters Nos. 71 and 72 contained arsenic, and for this reason the average number of bacteria present was small. After the removal of this arsenic by filtration, bacterial life was abundant in the effluents.

As indicated in this table some of the sewages and effluents contained several million bacteria per cubic centimeter. It would have been impossible to count the colonies formed in gelatine plates by such great numbers of organisms, therefore the samples were diluted with known volumes of sterilized water before the analyses were made. By this method of treatment some of the species, represented by only a few cells in the liquors, were probably eliminated. However, by diluting the samples, the number of cells found in a cubic centimeter was reduced, making it easier to identify the colonies belonging to each species than it would otherwise have been. Certain bacteria liquefied the gelatine, others produced well-marked colors or colonies which had characteristic forms.

By taking advantage of the effect of dilution to diminish the number of bacteria on the plate and thus separate the colonies, and by noting the characteristics just described, about thirty-five different species have been detected in the various sewages and effluents. In

order to complete these determinations, detailed series of tests or analyses have been made of the most common forms.

To show the relative numbers of colonies which each of these species formed on the plates when present in the sewage or effluent examined, a table has been prepared which gives the average per cent. which the colonies belonging to any one species was of the entire number of colonies on the plate, whenever such species occurred. (See table, page 453.)

Number of Colonics belonging to a Single Species jound on a Plate compared with the Whole Number of Colonies on the Plate (Percentage).

* Whole number of species found.

† Number of speeles found in the sewage applied which appeared in the cfluent.

This table shows that eleven species were found in the sewage applied to filters Nos. 71 and 72, eight of which were detected in the effluents of filters Nos. 71, 72 and 73; of the six species found in the sewage applied to Filter No. 74, five were detected in its effluent; of the twenty-three species in the sewage applied to Filter No. 76, fourteen appeared in the effluent, and of the seventeen species found in the sewage applied to Filter No. 75, ten were found in the effluent. Furthermore, species numbered 63, 64, 65, 66, 67. 68, 80 and 81 were found in all the applied sewages and effluents, except in the sewage and effluent of Filter No. 74. This filter was flooded with liquor obtained by treating wool-scouring sewage with calcium chloride, straining out the precipitated sludge and neutralizing the filtrate with sulphuric acid, and when applied to Filter No. 74, as indicated in the table on page 446, contained on an average 19,000,000 bacteria per cubic centimeter, but as a result of the treatment, only six species. Of these, No. 94 deserves special mention from the fact that it occasionally appeared as almost the only species in the liquor and because it possessed the power to reduce nitrate (in bouillon) to nitrite in a marked degree.

Of the other eight species which were common to all the sewages and effluents, attention is called to Nos. 66 and 80. During the months of August and September the Bacillus No. 66 formed from 53 to 90 per cent. of the colonies found on the plates. October great numbers of small white colonies, formed by Bacillus No. 80, appeared in the sewages and effluents. This organism differed from the preceding in that it developed rather slowly in nutrient gelatine and possessed the power to reduce nitrate (in bouillon) to nitrite with great rapidity. Of the other species, No. 63 liquefied the gelatine, forming brown colonies resembling burnt umber in color, and seemed to resemble the Bacillus ruber described by Eisen-Species 64 produced orange colonies and reduced nitrate (in bouillon) to nitrite rapidly. No. 65 liquefied the gelatine, reduced nitrate (in bouillon) to nitrite and was accompanied by a characteristic odor. Species 67, 68 and 81 liquefied the gelatine but possessed no other characteristics of special interest.

It will be seen that the doses for filters Nos. 75 and 76 contained many more species than the other sewages. This was undoubtedly due to the fact that the sewages applied to filters Nos. 75 and 76 were mixtures of regular Lawrence sewage and factory sewage.

The species present resembled the species in regular sewage closely, and the bacteria per cubic centimeter averaged about the same in number.

In this connection it should be noted that the pail used to measure the regular station sewage, to be mixed as described above, was sometimes used to measure the sewages to be applied to filters Nos. 71, 72, 73 and 74. The small volume of sewage left in it was sufficient probably to seed the liquors, measured later, with the bacteria which prevailed in the station sewage. This may account for the similarity of species found in these liquors.

Increase in the Number of Bacteria in Sewages which have been allowed to stand for Several Days.

The table on page 451 shows that the average number of bacteria per cubic centimeter found in the sewage applied to filters Nos. 71 and 72, during the period from August to December, averaged 39,-944. In the table on page 433 the average number of bacteria is given as 1,668,743 per cubic centimeter, but this latter table includes an average of the analyses made from May to December. The apparent discrepancy shown by these two tables is due to the fact that the amount of arsenic in the sewage has varied at different seasons of the year. Sewages obtained at certain seasons (May or December, for instance) sometimes contained several million bacteria per cubic centimeter, but at other times the number found averaged less than 20,000.

When such sewage is filtered, the arsenic is removed and the bacteria increase rapidly in the purified effluent, as shown in the next table.

Comparison of the Number of Bacteria which developed in Sewage from Tannery No. 1 with the Effluents from Filters Nos. 71, 72 and 73.

[Bacteria per Cubic Centimeter in the Sample.]

| | | | | | Immediately after Collection. | After Stand- ing 24 Hours. | After Stand- ing 48 Hours. | Arsenic (Parts per 100,000). |
|-------------------|--|--|---|--|-------------------------------------|----------------------------------|----------------------------------|------------------------------------|
| Tannery sewage, | | | ٠ | | 2,652 | 438 | 200 | 2.0 |
| Effluent from 71, | | | | | 5,040,000 | 5,180,000 | 5,200,000 | Less than 0.1 |
| Effluent from 72, | | | | | 5,610,000 | 18,860,000 | 28,800,000 | 0.1 |
| Effluent from 73, | | | | | 529,000 | 575,000 | 1,250,000 | 0.1 |

This table shows that when much arsenic was present the bacteria were few in number, but in the effluents which contained a mere trace of arsenic the bacteria increased rapidly, for a time at least.

Wool-scouring Liquors.

The sewage from wool scouring usually contained a large excess of free alkali and organic substances washed from the wool. Before applying the sewage to Filter No. 74, the liquor was treated with calcium chloride and strained, in order to remove the matters in suspension. The strained liquor, obtained in this way, was then neutralized by adding sulphuric acid, and applied to Filter No. 74, or mixed with station sewage and applied to Filter No. 76.

The bacteria in the untreated liquor included several species; in the strained liquor the number of species was smaller; in the neutralized liquor there were only a very few species; and in the neutralized liquor mixed with station sewage, to make the dose for Filter No. 74, a great many species appeared. When these liquors were allowed to stand for a few days the number of bacteria increased rapidly. This point is well illustrated in the following table:—

Number of Bacteria per Cubic Centimeter found in Wool-scouring Sewages.

| | Untreated Wool-scouring Llquor. | Liquor plus Calcium Chloride strained. | Strained Liquor neutralized by adding Sulphuric Acid. | Neutralized Liquor plus Sta- tion Sewage. |
|-----------------------------------|---------------------------------------|--|--|---|
| Sample just collected, | 10,000 | 100 | 200 | 1,942,000 |
| Sample stood twenty-four hours, . | 1,485,000 | 20,000 | 310,000 | 56,700,000 |
| Sample stood three days, | 119,600,000 | 10,000,000 | 57,000,000 | 71,940,000 |

From this table it is apparent that the number of bacteria contained in the various liquors increases most rapidly in the liquor which has been neutralized with acid. As shown elsewhere, however, the bacteria found in the neutralized liquor generally belonged to a small number of species, species No. 94 often forming nearly 90 per cent. of the colonies. The neutralized liquor was diluted to a greater degree than the other liquors, before making analyses, because this liquor was infested with moulds, and unless the samples had been diluted enough to reduce the number of moulds, the latter filled up the plates so that the bacteria could not be detected.

SEWAGE FROM TANNERY No. 2.

The samples of sewage obtained at Tannery No. 2 contained, on an average, several million bacteria per cubic centimeter. The sewage applied to Filter No. 75 contained a mixture of this tannery sewage with regular station sewage.

Average Number of Bacteria per Cubic Centimeter found in the Sewage from Tannery No. 2, in the Sewage applied to Filter No. 75, and in the Effluent from Filter No. 75.

| Tannery Sewage. | Sewage applied to Filter No. 75. | Effluent from Filter No. 75. |
|-----------------|----------------------------------|------------------------------|
| 3,943,000 | 6,511,000 | 26,700 |

The species found in the sewage applied to Filter No. 75 and in the effluent resembled the species found in regular station sewage.

In summing up these results, it may be said that the number of bacteria found in the various sewages and effluents was very great, except in the tannery sewage, which contained arsenic; when this arsenic was removed the bacteria began to increase rapidly in numbers. The species found resembled the species found in regular sewage, and most of the species found in the sewages appeared in the effluents. A few species were found in all the sewages and effluents.

MICRO-ORGANISMS FOUND IN RIVER WATER RECEIVING THE SEWAGE FROM TANNERY No. 1.

Samples of water, collected from different points of the river, into which the sewage from tannery No. 1 runs, were examined for micro-organisms with the following results. This sewage, it will be remembered, contains arsenic.

Micro-organisms in Sample of Water collected at a Point in the River.

| Above Tannery. | Tannery Sewage. | 1,000 Feet below Tannery. | Head of Pond through which the River flows. | Near the Outlet of the Pond. |
|----------------|---------------------------|------------------------------|---|------------------------------|
| Diatoms, | Diatoms, | Diatoms, | Diatoms, | Diatoms. Algæ. |
| Cyanophyceæ, | Cyanophyceæ, . Infusoria, | Cyanophyceæ, . Infusoria, | Cyanophyceæ, . Infusoria, | Cyanophycess. Infusoria. |

From this table it is apparent that after the tannery sewage enters the river the alge disappear until the water has become partially purified by passing through the pond. Most of the cyanophyceæ and diatoms found in the river above the tannery also disappeared, but there were some micro-organisms, such as nostoc, navicula and infusoria, found even in the undiluted sewage.

The river above the tannery contained great bunches of alge, cyanophycee, etc., and the stones on the bottom were coated with masses of zoöglea, about which were clustered diatoms of many varieties and also infusoria. The alge included spirogyra, ulothrix and other filamentous forms; cosmarium, chlorococcus and other non-filamentous forms; the cyanophycee included oscillaria, leptothrix, edogonium, nostoc and other forms; the diatoms included navicula, synedra, gomphonema, tabellaria and many other forms; indeed, the diatoms were very common; the infusoria included at least three forms.

The surface of the river below the tannery, its banks and the stones which line the pond were coated with masses of a dark-green slime. On the bottom of the river and pond bunches and mats of dirty white filamentous forms had gathered, which often looked like frayed rope. These masses of slime and bunches or mats consisted of filaments of oscillaria, gleeotrichia, lyngbia, protococcus forms, zoöglea, diatoms, sludge from the tannery, infusoria, worms, etc., matted together. Most of the filamentous forms found belonged to the blue-green algæ, but associated with the latter, especially in the clusters of dirty-white rope-like bunches found on the stones, were long, cork-screw-like filaments, nearly white, which possessed marked They resembled beggiatoa in general appeartwitching movements. ance, but, from the presence of many similar filaments containing distinct chlorophyl bands, the white cells perhaps were filaments of oscillaria from which the chlorophyl had been bleached by the sulphur compounds set free by decomposition of the tannery sewage.

Where the stream becomes purified by sedimentation, new species of cyanophyceæ, such as oscillaria, glæotrichia, new forms of diatoms and infusoria, notably vorticella, were found. Some of these may have been introduced by the tide-water which floods the basin twice a day.

After receiving tannery sewage the character of the plant life changed; the organisms decreased in number and in species. Experiments therefore were made in order to test the effect produced

by varying volumes of tannery sewage on the micro-organisms living in the river water.

Various amounts of sewage from the settling basin at tannery No. 1 were added to flasks containing samples of water taken from the stream above the tannery. A similar series of flasks was treated with a sodium arsenite solution containing arsenic in the proportion of 980 parts, 495 parts and 248 parts per 100,000 parts of river water. As noted above, the stream contained very many species of micro-organisms.

The algæ seemed to die out after standing two or three days in waters containing the greatest amounts of sewage or arsenite, but lived for several days in the other samples. In flasks which contained small amounts of sewage or arsenite, infusoria and diatoms, especially synedra and navicula, seemed to increase; even spirogyra, etc., lived there for two weeks. As a matter of fact one species of algæ, which resembled protococcus or tetraspora, flourished for five months in a flask which contained 1 part of tannery sewage to 1 part of river water.

Effluents from filters Nos. 71, 72 and 73 produced no particular effect on micro-organisms present in pond, river and well waters, but large quantities of tannery sewage or a strong solution of arsenite destroyed such organisms as cosmarium, etc. Even in these solutions, however, certain filamentous forms and diatoms lived.

Number of Bacteria per Cubic Centimeter found in Water collected at Different Points in the River, September, 1896.

| Stream above Tannery. | Tannery Sewage. | Stream 1,000 Feet below Tannery. | Head of Pond. | Near Outlet of the Pond. |
|--------------------------|-----------------|-------------------------------------|---------------|-----------------------------|

FILTRATION OF LAWRENCE SEWAGE.

The Lawrence sewage applied to the experimental filters is drawn through a 2.5 inch pipe 4,300 feet long, from the Lawrence Street sewer at a point just below the main business street of the city and just above the entrance of wastes from the large mills. This sewer drains the streets, houses and stores of the most densely populated section of the city.

The sewage drawn from this sewer has contained more organic matter during 1896 than during any previous year in the history of the station with the exception of 1895.

Large measuring tanks receive this sewage at the station and from them it is run upon the different filters. On at least four days in each week a bottle of sewage is collected for analysis from one of these tanks, and this is known as the regular sewage.

Monthly Averages of Analyses of Regular Sewage Samples.

Analyses of samples of sewage collected each Wednesday directly from the Lawrence Street sewer, at the point where the pipe from the sewer to the station begins, have been made each week during the year. These samples have been collected in the morning when strong day sewage is flowing through the sewer. The table giving the monthly averages of the analyses of this sewage is given below, and on comparing it with the previous table it will be seen that the total nitrogen represented by the free and albuminoid ammonia is nearly the same, being 4.86 parts in the Lawrence Street sewage and 4.62 parts in the regular station sewage. The greater quantity of free ammonia and the lower quantity of oxygen consumed in the regular sewage are due to its passage through the pipe from the sewer to the station, with the consequent bacterial and chemical changes. The nitrates, nitrites and free dissolved oxygen present in the sewage when in the sewer have disappeared when the sewage reaches the station.

The second table beyond gives a monthly average of samples collected from the Lawrence Street sewer each week day during eight months of the year. The samples averaged in this table were taken

at all times of the day, both morning and afternoon, while the samples averaged in the first table beyond were all taken at about 9 o'clock in the morning.

OTHER SAMPLES OF SEWAGE COLLECTED FOR ANALYSIS.

In addition to the sewages represented by the preceding tables, it has been the practice to collect other representative samples for analysis, as follows:—

- 1. A sample representing an average of all the sewage pumped on each Tuesday of the year.
- 2. Samples representing weekly averages of all the sewage applied to filters Nos. 1, 6 and 9 A.
- 3. On each Tuesday of the year a sample of the supernatant sewage after allowing regular sewage to stand for four hours.
- On each Tuesday of the year a sample of the supernatant sewage after treating regular sewage with sulphate of alumina in the proportion of 1,000 pounds per 1,000,000 gallons, and allowing to stand and settle for four hours.
- 5. On each Tuesday of the year a sample of the sewage resulting from straining regular sewage through a layer of coke breeze at a rate of 1,000,000 gallons per acre daily.

Monthly Averages of Analyses of Average Sewage Samples. [Parts per 100,000.]

Summarizing these results for 1896 we find that, by allowing the sewage to settle in barrels for four hours and then drawing a sample for analysis from a faucet half way between the top and bottom of the barrel, this sample shows a removal of 33 per cent. of the organic matter as represented by the total albuminoid ammonia and 27 per cent. as represented by the oxygen consumed. By the same treatment, together with the addition of sulphate of alumina, in the proportion stated, the removal has been 53 per cent. and 51 per cent. respectively. By straining through coke the removal has been 47 and 49 per cent. respectively.

These continuous experiments upon the removal of organic matter by sedimentation, chemical precipitation and straining through coke have been continued for several years, and the results obtained each year are presented in the following table:—

^{*} In some cases the fats given under "regular sewage" are of the average sewage.

The sewages resulting from settling, precipitating and straining the regular sewage have been applied to filters Nos. 13 A, 14 A and 19, respectively, as will be described beyond. The percentage of organic matter removed by these different methods varies from year to year and depends largely upon the percentage of insoluble organic matter in the sewage treated. Thus, in 1892, 55 per cent. of the total albuminoid ammonia was insoluble and sedimentation removed 33 per cent.; in 1893, 51 per cent. was insoluble and chemical precipitation removed 48 per cent.; in 1894, 59 per cent. was insoluble and sedimentation, chemical precipitation and coke straining removed 30 per cent., 59 per cent. and 43 per cent. respectively; in 1895, 72 per cent. was insoluble and the removal by these three processes was 48, 63 and 61 per cent. respectively; while in 1896, with 62 per

cent. of the total albuminoid ammonia insoluble, the per cent. of removal by the three processes has been 33, 51 and 47 respectively.

COMPARISON OF THE STRENGTH OF STATION SEWAGE.

Bringing together for comparison the average results of the analyses of the several series of samples of untreated sewage gives us the following table: -

COMPOSITION OF SEWAGE.

The percentage of the nitrogen in a sewage, determined by the albuminoid ammonia process, varies with the age of a sewage, that is, with its freshness or staleness. Figures in regard to this fact have been given in the last two reports, and the subject has been further studied during 1896, not only with fresh and stale city sewage but also with the various manufacturing sewages examined.

A continuous comparative determination, by both the albuminoid ammonia and Kjeldahl processes, of the organic nitrogen present in the stale sewage pumped at the station and the fresh Lawrence Street sewage has been made. This examination continued for five months. June to October inclusive, and the results are presented in the following table: -

Comparison of Nitrogen determined as Albuminoid Ammonia (Wanklun) with Organic Nitrogen (Kjeldahl).

| | | | | | | | | | Station Sewage. | Lawrence Street Sewage. |
|---|---|---|---|---|---|---|---|---|-----------------|----------------------------|
| Nitrogen as albuminoid ammonia, | | | | | | | | | 0.41 | 0.94 |
| Organic nitrogen, Per cents which former is of latter, | | | | : | : | : | | : | 1.02 43 | 2.56 37 |
| Average per cent., 1894-95, | • | • | • | • | • | • | • | ٠ | 39 | 26 |

The figures given in the previous years have shown a smaller percentage of nitrogen determined by the albuminoid ammonia process. These former figures have been calculated from analyses of series of samples taken each hour for twenty-four hours and cover a period of one day only, but include, of course, all the various kinds of sewage, weak and strong, flowing in the sewer during that day. On the other hand, the 1896 figures cover a five months' period, but are of samples of morning sewage only, and it has been found that this strong sewage yields a larger percentage of its organic nitrogen as albuminoid ammonia than does the weaker night sewage. A larger percentage of the organic matter present was in solution in 1896 than during previous years, and this fact probably had considerable influence upon the percentage determined by the albuminoid ammonia process.

MANUFACTURING SEWAGES.

Bringing together the comparative determinations made by both the Wanklyn and Kjeldahl processes of the nitrogen in the manufacturing sewages gives us the following table:—

Comparison of Nitrogen determined as Albuminoid Ammonia (Wanklyn) with Organic Nitrogen (Kjeldahl).

| ſ | Po | rta | per | 100 | იიი | - |
|-----|----|------|-----|-----|------|---|
| - 1 | Fa | rts. | per | LUU | OUU. | 1 |

| | | Entire Sewage of Tannery No. 1. | Supernatant Sewage of Tannery No. 1. | Entire Sewage of Tannery No. 2 | Supernatant Sewage of Tannery No. 2. | Wool- scouring Liquor (clarified). |
|--------------------------------------|---|---------------------------------|---|--------------------------------|---|---|
| Nitrogen as albuminoid ammonia, . | : | 5.09 | 2.20 | 2.71 | 1.85 | 9.38 |
| Organic nitrogen (Kjeldahl), . | | 14.17 | 5.71 | 5.92 | 4.54 | 21.90 |
| Per cent. which former is of latter, | | 36 | 39 | 46 | 41 | 43 |

The analyses of the tannery sewages were made as soon as the samples were received at the laboratory, but this was generally twenty-four hours after their collection, although occasionally they were received upon the day of collection. This fact gave a lengthened period for decomposition and the consequent breaking up of organic matter into bodies more easily oxidized by the permanganate used in the Wanklyn process, but had little influence upon these particular results, for tannery sewage is of considerable age and in an advanced state of decomposition when allowed to run to waste from the tannery. Besides this the samples of sewage from tannery No. 1 almost invariably contained enough arsenic to stop further decomposition.

DISPOSAL OF FRESH AND STALE SEWAGE.

In regard to the changes in the organic constituents of sewage that take place as the sewage grows older, it can be said that considerable data have been given in the last two reports. It has become evident, and has been so stated in part, that when sewage is fresh, that is to say, when the mixture of water and decomposable matter of all kinds such as is found in sewage has just occurred, these matters can be strained or precipitated out quite readily from the main body of the liquid. This is the reason why it has been stated by many that sewage should reach its disposal area as soon as possible, that is, in as fresh a condition as possible, in order that this separation may be accomplished with the best results. The separated sludge then remains to be cared for either by disposal upon separate sludge beds or mixed with earth and a compost formed. The disposal upon sludge beds often means simply that it is allowed to run upon these beds and by draining become separated from the large percentage of water contained in it, after which it is scraped from the bed and composted. If the entire sewage is allowed to run upon the main beds the crude, insoluble organic matters are strained out upon the surface of the beds, and, accumulating, need to be disturbed frequently or scraped from the surface. If, on the other hand, the sewage is stale and has undergone comparatively long-continued mechanical, chemical and bacterial actions, not only is the crude organic matter more finely divided and hence more readily enters the interstices of the filtering material as stated in the last report of the Board, but the sewage has actually lost crude organic matter both by the change of organic nitrogen into free ammonia and also by the reduction of the organic matters, measured by the oxygen consumed, on account of the formation and liberation of gaseous compounds of carbon. For example, the table given on page 461 of the report of the Board for 1894 shows that when a bottle of fresh sewage was allowed to stand for twenty-four hours the organic nitrogen (Kjeldahl) decreased 51 per cent. and the oxygen consumed 25 per cent., while the free ammonia increased over 100 per cent.

To illustrate the difference in the disposal of fresh and stale sewage two small tube filters containing equal depths of the same grade of sand were put in operation in May. To one of these filters sewage taken directly from the city sewer and brought immediately to the station has been applied, while the other has received the sewage pumped at the station. The average monthly analyses of the two sewages is given in the following table:—

| [Parts p | er 10 | 0,000. |] |

Comparing these tables of sewages and effluents it will be seen that the total nitrogen applied to these filters was nearly equal in both cases, but that 42 per cent. of the nitrogen applied to Filter F was found in the effluent of that filter, while the effluent of Filter H contained only 33 per cent. of the nitrogen applied. These figures are of the nitrogen in the forms given in the table, but the fresh sewage applied to Filter H invariably contained nitrogen as nitrates; these nitrates averaged .15 part per 100,000, and this added to the average total nitrogen given makes this average 4.50 parts per 100,000, and the percentage of nitrogen found in the effluent 32.

An examination of the sand of each filter at the close of the experiment showed that the sand of Filter F, which received the stale sewage, contained about 12 per cent. of the applied nitrogen, and the sand of Filter H, which received the fresh sewage, contained 26 per cent. of the applied nitrogen.

The upper 3 inches of sand in Filter F contained 38 parts per 100,000 by weight of nitrogen, and the similar sand of Filter H, 78 parts per 100,000.

These two filters were both operated at a high rate, considering the strength of the sewage applied, but Filter F, receiving a sewage having 75 per cent. of its nitrogen in the form of free ammonia, disposed of it more readily than Filter H, receiving sewage containing 42 per cent. of its nitrogen in the form of free ammonia.

PERMANENCY OF SEWAGE FILTERS.

There are now in operation at the station six filters, $\frac{1}{200}$ of an acre in area and containing different grades of filtering material, which have been in operation for periods varying from five to nine years. The actual number of gallons of sewage applied to these filters from their date of construction up to Jan. 1, 1897, is given in the following table:—

| | Fil | TER : | NUME | BER. | | Da | ate when Se | wage lied. | was | Actual Number of Gallons Applied. | Gallons per Acre. | |
|-----|-----|-------|------|------|--|-------|-------------|---------------|-----|-----------------------------------|----------------------|-------------|
| 1, | | | | ٠ | | Jan. | 10, 1888, | | ٠ | | 1,166,345 | 233,269,000 |

| ŀ, | | | | | | Dec. | 19, 1887, | | | | 392,685 | 78,537,000 |
| δA, | | | | | | Sept. | 14, 1891, | | | | 693,770 | 138,754,000 |
| ŝ, | | | | | | Jan. | 12, 1888, | | | | 753,249 | 150,649,800 |
| Α, | | | | | | Nov. | 18, 1890, | | | | 762,082 | 152,416,400 |

Filters Nos. 1, 6 and 9 A contain material with an effective size of 0.48, 0.35 and 0.17 millimeter respectively, and with these three filters the entire depth of material above their underdrains is of one kind. The material in filters Nos. 1 and 9 A is very uniform, while the material in Filter No. 6 varies from gravel to sand. These three filters on Jan. 1, 1892, after four years' operation of Nos. 1 and 6 and one year of No. 9 A, had had applied to them and had stored the following amounts of nitrogen:—

Nitrogen in Pounds.

| | | | | | | | Applied. | Stored. |
|-----------------|--|--|--|--|--|--|----------|---------|
| Filter No. 1, . | | | | | | | 104.5 | 16.0 |
| Filter No. 6, . | | | | | | | 66.0 | 11.8 |
| Filter No. 9 A, | | | | | | | 38.5 | 8.4 |

On Jan. 1, 1897, these three filters, after nine years' operation of Nos. 1 and 6 and five years' operation of No. 9 A, had had applied to them and contained the following amounts of nitrogen:—

Nitrogen in Pounds.

| | | | | | | | Applied. | Stored, |
|-----------------|--|--|--|--|--|--|----------|---------|
| Filter No. 1, . | | | | | | | 333.0 | 17.0 |
| Filter No. 6, . | | | | | | | 250.0 | 22.0 |
| Filter No. 9 A, | | | | | | | 249.0 | 17.0 |

Between January, 1892, and January, 1897, 9 inches of sand were removed from the surface of Filter No. 1, 5 inches in June, 1892, containing 8.73 pounds of nitrogen, and 4 inches in May, 1893, containing 10,50 pounds. The amount of nitrogen stored in this filter between January, 1892, and May, 1893, increased so rapidly that after this removal of 19.23 pounds, 3 pounds more than the entire amount of nitrogen stored in the filter upon Jan. 1, 1892, the filter still contained 10 pounds of nitrogen. At the end of 1896, however, three and one-half years after this last removal of clogged sand, no more nitrogen was stored in the lower 54 inches of sand of the filter than in May, 1893, and the upper 9 inches of the filter, the new material added in May, 1893, contained a little less nitrogen than it did one year after being placed in the filter.

Filter No. 6 stored nitrogen quite steadily, and in May, 1892, 2 inches of sand containing 2.7 pounds, and in September, 1893, 2 inches containing about 3.8 pounds of nitrogen were removed from the surface of the filter. Four inches of clean sand were added to the filter to take the place of that removed, but within a year the stored nitrogen had increased to about the amount now present in the filter.

Filter No. 9 A, during a portion of 1892 and 1893, was used for experimental purposes to show the effect of repeated scraping of the surface when elogged instead of the weekly raking given the other filters. On March 14, 1893, it was filled to its original depth, and during the past two years the amount of stored nitrogen present has varied but not increased, an examination at the end of 1896, showing the same amount as in March, 1895.

Since 1893 there has been no removal of filtering material from any of these large experimental filters, and the removal or destruction of the large amount of organic matters of the sewage has been accomplished without impairing the action or shortening the life of the filter. That is to say, this organic matter has either passed from the filters into the air in gaseous forms of carbon and nitrogen or has united with a base and passed away in the effluent in the form of mineral salts in solution.

EXPERIMENTS UPON STORAGE AND LOSS OF NITROGEN.

It was found in the beginning of these investigations that a varying proportion of the nitrogen applied to the filters was not stored in the filtering materials, neither did it pass away in the effluent. Quite a large number of examinations of filtering materials, which had been in use in the filters, for the determination of the nitrogen present, together with determinations of the nitrogen applied, and coming away in the effluent, indicated that 30 per cent. of the applied nitrogen was unaccounted for. Therefore 30 per cent. of the nitrogen was considered to have passed into the air in gaseous forms.

Tables were given in the reports of 1893 and 1894 to show the storage or loss of nitrogen by the different filters, and in making the calculations for the figures presented in the tables this 30 per cent. factor was used; that is to say, to the total nitrogen found in the effluent of each filter 30 per cent. was added and this sum compared with the total nitrogen in the applied sewage. These tables were of value and gave an approximation of the actual storage or loss of nitrogen. As this 30 per cent. factor, however, was determined by examining small samples of sand taken from the large amount in the filters, further investigations in regard to storage and loss of nitrogen have been made. Another reason for investigation was the fact that these tables showed a great storage of nitrogen in some of the filters of fine material which continued in efficient service.

For this experiment three small tube filters were started, each filled with sand of a different effective size, the total amount of sand used in each filter being so small that it could all be mixed in a pail and representative samples obtained. These filters were operated for six months and nitrification was active in each of them. An average sample of all sewage applied was collected and analyzed, the organic nitrogen being determined by the Kjeldahl process; the entire effluent of each filter was collected and analyzed, and at the end of the experiment the entire body of sand in each filter was examined for nitrogen present.

These three filters were known as E, F and G. E was of sand of an effective size of 0.04 millimeter, F of sand of an effective size

of 0.17 millimeter, and G of sand of an effective size of 0.48 millimeter. Filter E received sewage at the rate of 25,000 gallons per acre daily and filters F and G at the rate of 50,000 gallons per acre daily.

The average total nitrogen in the sewage used is shown by the following table. The total nitrogen is the organic nitrogen, determined by the Kjeldahl process, plus the nitrogen of the free ammonia.

Average Total Nitrogen in Sewage applied to Filters E, F and G.

Of the nitrogen applied to E, 33 per cent. appeared in the effluent but there was no increase in the amount of nitrogen stored in the sand, thus leaving 67 per cent. of the applied nitrogen unaccounted for.

Of the nitrogen applied to F, 46 per cent. appeared in the effluent and 12 per cent. was stored in the sand, leaving 42 per cent. unaccounted for.

Of the nitrogen applied to G, 44 per cent. was found in the effluent but there was no increase in the amount of nitrogen stored in the sand, thus leaving 56 per cent. unaccounted for.

These experiments were carried on during the warmest six months of the year, and the disappearance of nitrogen was, of course, greater than would be the average for the entire year, but the results are interesting and point towards two conclusions: First, that with a filter of fine sand by which a considerable percentage of the organic matters is strained out and held near the surface, a larger proportion of nitrogen passes into the air in gaseous forms than is the case with a filter of coarse sand. Second, that of two filters of comparatively coarse sand into which the sewage penetrates easily, the one in which the air circulates most freely will store the least nitrogen.

REMOVAL OF SLUDGE FROM SEWAGE.

Studies of different methods of removing sludge have been continued throughout the year, as follows: —

1. Rapid filtration through coarse gravel with the aid of a current of air drawn down through the gravel.

- 2. Rapid filtration through coarse gravel with the aid of a current of air forced up through the gravel.
 - 3. Sedimentation.
 - 4. Chemical precipitation.
 - 5. Straining through coke.

Discussion of the Several Methods.

Forced Filtration with Aeration.

The gravel filters 15 B and 16 B, receiving sewage at a very high rate in gallons per acre and aerated by means of a current of air drawn down through them, have been continued in operation. These filters were first put in operation in July, 1892, and since the first part of 1893 filtration has been aided by the air current. time the aspirators were attached to the filters until September, 1894, air was constantly drawn down through these filters, $\frac{1}{200000}$ of an acre in area, at the rate of about one gallon every four minutes. On the latter date the method of aeration was changed so that the filters were aerated only at night for twelve or sixteen hours. results have been obtained by this method of filtration and aeration, and the filters, operating at average rates of about 450,000 gallons per acre daily during 1893, 1894 and 1895, and 350,000 gallons per acre daily during 1896, have shown on different years a removal of organic matter of the applied sewage varying from 60 to 85 per cent. A large proportion of this removed organic matter has been oxidized within the filter, but enough has accumulated from time to time in the filters to render its removal necessary if the filters were to be continued in service. This removal has been accomplished, on several occasions during 1894 and 1895, by flushing the filters out with city water or removing the entire filtering material and washing it. Early in 1896 the filters again became so badly clogged by the storage of organic matter that it was necessary to remove it. ing the filters to rest and increasing the air supply was resorted to, but apparently this had little effect upon the organic matter, for, upon starting filtration of sewage again, nitrification could not be established. As an experiment, city water was applied at a low rate for a few days and the filters aerated. In this medium nitrification in Filter 15 B became active, and the stored organic matter was nitrified and carried away in the effluent in such an amount that the filter has since been in good condition and successful operation.

Filter 16 B, however, was so badly clogged that the filtering material had to be removed and washed.

The rate of filtration has been lower during the remainder of 1896, in order to avoid, if possible, this storage of organic matters in the filters.

Filtration through Gravel with a Current of Air forced up through the Gravel.

Experiments carried on during 1895, upon rapid filtration through gravel and coke aided by a current of air forced up through the filters by a fan blower, were described in the report for that year.

One result of this experiment was to prove that the fan blower could not force air through the clogged surfaces of the filters, as of course was necessary if the air in the main body of the filtering material was to be frequently renewed.

Early in 1896 a somewhat similar experiment was started. A filter containing 5 feet in depth of gravel of the same grade as in filters 15 B and 16 B was constructed and the air supply was forced up through the filter by means of a pressure pump. This pump is run by electric power and pumps slightly more than 18 gallons of air per minute, as determined by careful measurements. The filter has received sewage at the rate of 352,000 gallons per acre daily in ten equal doses between 7 A.M. and 5 P.M. It has been aerated between each application of sewage for fifteen minutes, making a total period of aeration of one hundred and fifty minutes daily, and the total quantity of air pumped into the filter 2,700 gallons daily, or three and one-half times the entire capacity of the filter tank when empty and about eight times the air capacity or open space of the filtering material when in position.

From the beginning of operation of the filter nitrification has been active and fully equal to that obtained in filters Nos. 15 B and 16 B, but the percentage removal of organic matter has not been equal to that obtained by these filters. This is owing to the fact that the effluents of 15 B and 16 B pass through trapped outlets and are better strained, while Filter No. 66 has very many openings or outlets for its effluent, and the organic matter, not nitrified or lost into the air, passes down through these outlets instead of being strained out and stored, as is the case in 15 B and 16 B. (For details of operation of Filter No. 66 see page 502.)

Further Purification of the Effluents of Filters 15 B, 16 B and 66.

This rapid filtration gives at best but partially purified effluents, and the rate at which these effluents can be further purified by ordinary sand filtration has been continuously studied, together with the preliminary filtration. Filter No. 12 A, containing 5 feet in depth of sand of an effective size of 0.19 millimeter, has received the combined effluents of filters Nos. 15 B and 16 B for the past five years. The highest average rate, in gallons per acre daily, obtained by this filter was in 1893, -745,000 gallons. (See table and discussion, page 482, report of 1895.) Its rate during 1896, exclusive of the month of May, when it was resting, has been 478,000 gallons per acre daily As these three filters, Nos. 12 A, 15 B and 16 B, are of the same area, the rate for the combined area has been 160,000 gallons per acre daily. The effluent of Filter No. 12 A has been of most excellent quality (see page 493). The effluent of Filter No. 66 has been applied to Filter No. 67, containing 5 feet in depth of sand of an effective size of 0.19 millimeter. The average rate of filtration obtained by this filter has been 608,500 gallons per acre daily. As Filter No. 66 is of twice the area of Filter No. 67, the rate for the combined area has been 203,000 gallons per acre daily. This rate has been maintained with difficulty, the surface of No. 66 needing constant attention and the removal of a large amount of clogged sand. (For details of operation see page 502.)

Sedimentation.

For several years the supernatant sewage obtained by allowing regular sewage to stand and settle for a definite period has been applied to a sand filter. This filter is known as Filter No. 13 A and in 1893 received sewage at the rate of 416,000 gallons per acre daily. This rate was reduced to 240,000 gallons per acre daily in January, 1894, and on July 1 of the same year to 160,000 gallons per acre daily, at which rate the filter has since been operated.

The sewage applied to this filter at the present time is fully as strong in units of unoxidized nitrogen as was the regular sewage during the first years of operation of the station.

The effluent of the filter has been of a satisfactory quality, but the nitrogen stored in the filtering material is increasing. (For details of operation of Filter No. 13 A see page 495.)

Chemical Precipitation.

Since January, 1893, the supernatant sewage from regular sewage which has been allowed to settle for four hours after treatment with crude alum, at the rate of 1,000 pounds per million gallons, has been applied to a sand filter. This filter contains 5 feet in depth of sand of an effective size of 0.17 millimeter. During 1893 the average rate of filtration was 267,000 gallons per acre daily, with a maximum rate of 640,000 gallons during November. This rate was reduced on Jan. 1, 1894, to 360,000 gallons per acre daily, and upon July 1 of the same year to 200,000 gallons per acre daily, at which rate the filter has since been operated.

The quality of the effluent of this filter has been almost uniformly satisfactory, but the stored nitrogen of the filter is slowly increasing. (For details of operation of Filter No. 19 during 1896 see page 497.)

Straining through Coke.

Since June 1, 1894, sewage which has passed through a thin layer of coke breeze has been applied to a sand filter containing 5 feet in depth of sand of an effective size of 0.19 millimeter. During 1894 the rate of application was 345,000, during 1895 307,000, and during 1896 280,000, gallons per acre daily.

The effluent of the filter has been of a satisfactory quality, but the nitrogen stored in the filter is gradually increasing. (For details of operation of Filter No. 14 A during 1896 see page 496.)

Conclusions.

The chief benefit derived from the method of rapid filtration and aeration is the destruction of a considerable percentage of the crude organic matter or sludge contained in the sewage. By sedimentation or chemical precipitation we only concentrate this sludge in a small volume of the sewage. It is true, however, that we do not by the amount of aeration given our coarse filters destroy all the crude organic matter of the sewage, as some comes away in the effluent and some remains stored in the filters. With more aeration a larger proportion of this organic matter would be oxidized, but not an amount proportional to the increased aeration. The results obtained here and elsewhere with this method have been remarkable, but its practical operation depends upon obtaining the high efficiency of the coarse filters at a reasonably low cost for the power used to

supply the air current, and our experiments have tended to show that this cost is prohibitive. Our best results with this method gave a quantitative efficiency of 248,000 gallons per acre daily as calculated upon the total area of gravel and sand filters. (See page 482, report of 1895.) This was with newly constructed filters and a sewage not as strong as that which is now pumped at the station. This rate is no greater than that at which newly constructed filters, receiving the supernatant sewage from sedimentation or chemical precipitation, can be operated, and it is reasonably certain that the sludge resulting from these methods can be taken care of more cheaply than it can be oxidized or burnt up in the aerated gravel filters. When coke breeze can be obtained and the sewage given a preliminary treatment before sand filtration by being passed through this breeze at a high rate in gallons per acre daily, the organic matters of the sewage can be removed from the entire body of the sewage as completely as chemical precipitation removes them from the main body of the sewage. There is no resulting sludge liquor from this coke-straining process, and the clogged coke can be removed from time to time and burned, the sludge being, of course, held by it and burned with it.

YEARLY AVERAGES.

The eight following tables present the average analyses of "regular" sewage for each year of operation of the station, together with the average yearly analysis of the effluent of each of the large filters 200 of an acre in area, during their entire period of operation up to Jan. 1, 1897.

Comparison by Years of the Composition of "Regular" Sewage obtained at the Experiment Station, with the Average Quantities pumped and the Local Annual Rainfall.

[Parts per 100,000.]

| YEAR. | Average Quantity of Sewage Filtered. Gallons per Day. | Annual Rainfall. Inches. | Free Ammonia. | Total. | Soluble. | Insoluble. | Chlorine. | Oxygen | Total Nitrogen. | Bacteria per Cable Centi- meter. |

ASHES OR CINDERS AS FILTERING MATERIALS.

Towards the close of the year two filters were put in operation, one containing 4.5 feet in depth of coal ashes and the other containing the same depth of cinders; that is, coal ashes from which the finer material has been removed. Cinder filters are in use in many places in England for rapid filtration of sewage and are known as "roughing" filters, and the material is valuable for filtration purposes wherever land of a suitable character cannot be found, or for preliminary filtration before disposal upon land; but the first systematic experiment in this country upon their use for the complete purification of sewage by intermittent filtration was made by Prof. Chas. MacMillan of Princeton University, to whom we are indebted for the suggestion.

The two filters at the station are known as filters Nos. 80 and 81. Filter No. 80 is of ashes and receives sewage at the rate of 70,000 gallons per acre daily. The effluent of the filter has been clear and bright from the beginning of the experiment, but nitrification did not begin until after the close of the year. Filter No. 81 is of cinders and has received sewage at the rate of 550,000 gallons per acre daily. (For details see page 504.)

AVERAGE PURIFICATION OF LAWRENCE SEWAGE BY THE SEVERAL FILTERS IN 1896.

The following table gives the average results obtained by the filters receiving Lawrence sewage during 1896. The qualitative efficiency of the filters is shown by the percentage removal of organic matters of the applied sewage as indicated by the albuminoid ammonia and oxygen consumed.

Average Per Cent. of Albuminoid Ammonia, Oxygen consumed and of Bacteria removed from the Sewage by the Several Filters, with Average Rutes of Filtration, 1896.

WORK OF THE FILTERS FOR 1896.

Filters Nos. 1 to 10, inclusive, are each one two-hundredth of an acre in area and are out of doors; filters Nos. 12 to 21 A, inclusive, are one twenty-thousandth of an acre in area and within the buildings; Filter No. 59 is one ten-thousandth of an acre in area, Filter No. 66, one three-thousandth of an acre in area, and Filter No. 67, one six-thousandth of an acre in area. These three filters are also within the buildings.

Filter No. 1.

This filter, containing 60 inches in depth of coarse sand of an effective size of 0.48 millimeter, was in good condition at the beginning of the year and nitrification was active. On Nov. 15, 1895, the filter was covered with canvas stretched over a frame and this cover was removed on March 12. The surface was spaded over 6 inches deep on April 6 and again on October 23. During the last week of October following this last spading no sewage was applied to the filter.

The physical condition of the filter was excellent throughout the year, the applied sewage passed readily from the surface and the character of the effluent was satisfactory, as shown by the following table, giving the monthly averages of the weekly analyses:—

Effluent of Filter No. 1.

Sewage applied, 300 gallons six times a week, except from Octoher 23 to November 6, when filter was allowed to rest. March 1 to 12, experiment interrupted by freshet. Surface raked 1 inch deep each week, except twice in January, once in December and during period of rest. Surface spaded 6 inches deep April 6 and October 23 March 12, canvas cover removed. June 13 to August 31, a trap 18 inches high was attached to effluent pipe. During March, 6½ inches of snow removed; during December, 6 inches of snow and 4½ inches of ice removed.

Filter No. 2.

This filter contains 60 inches in depth of fine sand of an effective size of 0.08 millimeter, with two trenches, 1 foot wide and 2 feet deep, of medium fine sand of an effective size of 0.19 millimeter. It has been in good condition throughout the year and has given a clear, bright, well-purified effluent.

The following table gives the monthly averages of the analyses of the effluent, and the notes below give the management of the filter during the year:—

Effluent of Filter No. 2. [Parts per 100,000.]

Sewage applied, 200 gallons six times a week, except from October 23 to November 6, when filter was allowed to rest. March 1 to 9, experiment interrupted by freshet. Surface of trenches raked 1 inch deep each week, except twice in January, once in February and once in December. February 6, surface of trenches dug over to a depth of 4 inches. March 21 and October 27, sand removed from trenches; sides of trenches scraped and raked, and bottom of trenches dug over to a depth of from 31 to 5 inches; sand replaced in trenches. August 1, cut grass and weeds on surface; weight of grass and weeds 170 pounds 8 ounces. Duriog January, 9½ inches of snow removed from entire surface and 4½ inches of ice from surface of trenches; during February, 14 inches of snow removed from entire surface and 2% inches of ice from trenches; during March, 6½ inches of snow removed from surface; during December, 7½ inches of snow removed from surface and 3½ inches of snow removed from surface and 3½ inches of ice from trenches.

Filter No. 4.

This filter contains 60 inches in depth of fine river silt of an effective size of 0.04 millimeter, with two circular trenches, about 14 inches wide and 12 inches deep, of coarse sand of an effective size

of 0.48 millimeter. The surface level of the trenches is a few inches lower than the surface of the remainder of the filter and upon it the sewage is applied. The filter has been in good condition throughout the year, has taken the applied sewage readily and given a clear, bright and well-purified effluent. During the summer the surface, with the exception of the trenches, was covered with a heavy growth of coarse grass; this was cut during August and the dry weight was at the rate of three tons of hay per acre.

The following table gives the monthly averages of the analyses and the notes below the management of the filter during the year:—

Sewage applied, 200 gallons three times a week, except from October 23 to November 6, when filter was allowed to rest. March 1 to 9, experiment interrupted by freshet. Surface of trenches raked 1 inch deep each week, except once in January and once in December. February 8, surface of trenches dug over to a depth of 4 inches. March 20 and October 27, sand removed from treuches; sides of trenches scraped and raked, and bottoms of trenches dug over to a depth of from 3 to 5 inches; sand replaced in trenches. August 1, cut grass and weeds on surface; weight of grass, 170 pounds 14 ounces. During January, $7\frac{1}{2}$ inches of snow removed from entire surface and $1\frac{1}{2}$ inches of ice from trenches; during February, 15 inches of snow removed from surface and 1 inch of ice from trenches; during March, 12 inches of snow removed from surface; during December, $8\frac{1}{3}$ inches of snow removed from surface and $4\frac{1}{2}$ inches of ice from trenches.

Filter No. 5 A.

This filter, of fine gravel stones of an effective size of 1.40 millimeters, has been in good condition and taken the applied sewage readily throughout the year. While the effluent is not equal in quality to effluents from the filters of finer material, yet it has contained on an average only 20 per cent. of the organic matter of the applied sewage.

The monthly averages of the analyses of the effluent are given in the following table and notes in regard to the operation of the filter are presented below:—

Sewage applied, January 1 to 6, 150 gallons twelve times a week; January 7 to 14, 600 gallons three times a week; January 15 to December 31, 300 gallons six times a week, except from October 23 to November 6, when filter was allowed to rest. March 1 to 10, experiment interrupted by freshet. Surface raked 1 inch deep each week, except once in January and twice in December. Surface dug over 6 inches deep on April 27 and November 17. June 13 to August 31, a trap 18 inches high was attached to effluent pipe. During January, 8½ inches of snow and 1½ inches of, ice removed from surface; during February, 17 inches of snow and 1½ inches of ice removed; during March, 12½ inches of snow removed; during December, 10½ inches of snow and 2½ inches of ice removed.

Filter No. 6.

This filter contains 44 inches in depth of mixed coarse and fine sand of an effective size of 0.35 millimeter. It has been kept in good physical condition throughout the year, has disposed of the applied sewage readily and has given an effluent of a satisfactory quality.

The following table presents the rate of filtration, the monthly averages of the analyses of the effluent and the notes below give the details of operation:—

Effluent of Filter No. 6.

Sewage applied, 300 gallons six times a week, except from January 6 to 14, when it was applied 600 gallons three times a week, and from October 23 to November 6, when filter was allowed to rest. March 1 to 9, experiment interrupted by freshet. Surface raked 1 inch deep each week, except twice in December. Surface dug over 6 inches deep March 31 and Augnst 31; from 6 to 8 inches deep on October 23, and 4 inches deep December 29. During January, 9½ inches of snow and 3½ inches of ice removed from surface; during February, 13½ inches of snow and 3½ inches of ice removed; during March, 12½ inches of snow and 8½ inches of ice removed.

Filter No. 9 A.

This filter contains 5 feet in depth of sand of an effective size of 0.17 millimeter. It has been in good condition throughout the year, has taken the applied sewage readily and has given an effluent of a satisfactory quality. The average rate of filtration has been 56,300 gallons per acre daily.

The following table gives the monthly averages of the analyses and the notes below give the details of operation for the year:—

Effluent of Filter No. 9 A.

Sewage applied, 300 gallons six times a week, except from January 1 to 15, when it was applied 600 gallons three times a week, and from October 23 to November 6, when filter was allowed to rest. March 1 to 9, experiment interrupted by freshet. Surface raked 1 Inch deep each week. Surface dug over 2 inches deep on February 4; 6 inches deep on March 31, June 15, August 31; 6 to 8 inches deep on October 23. From February 7 to March 31 four trenches 2 feet wide and 3 inches deep were cut in the surface. Durling January, 7 inches of snow and 63 inches of ice removed from surface; during February, 134 inches of snow and 34 inches of ice removed.

Filter No. 10.

This filter is one two-hundredth of an acre in area and contains 5 feet in depth of mixed coarse and fine sand of an effective size of 0.35 millimeter. No gravel underdrains are beneath the sand except directly above and around the outlet pipe. A partition, extending 3 feet below the surface, separates the quarter of the surface farthest from the underdrains from the remainder of the surface. To this quarter of the surface the sewage has been applied during 1896 at a rate of 120,000 gallons per acre daily for this quarter area, or 30,000 for the entire area of the filter. With this rate and method of construction and operation very satisfactory results have been obtained during the entire year.

The following table gives the monthly averages of the analyses and the notes below state the details of operation of the filter:—

Effluent of Filter No. 10. [Parts per 100,000.]

Sewage applied, 150 gallons six times a week, except from October 23 to November 6, when filter was allowed to rest. March 1 to 9, experiment interrupted by freshet. That part of surface to which sewage is applied has been raked 1 inch deep each week, except once in January and once in December. March 31, the entire surface dug over 6 inches deep; August 31, surface to which sewage is applied dug over 6 inches; October 23, surface to which sewage is applied dug over 8 inches and the remainder of surface 6 inches October 23, the grass and weeds pulled from the entire surface. During January, 8 inches of snow and 1 inch of ice removed from that part of surface to which sewage is applied; during February, 16½ inches of snow and ½ inch of ice removed; during March, 13½ inches of snow removed; during December, 12 inches of snow and 4½ inches of ice removed.

Filters Nos. 12 A, 15 B and 16 B.

Filter No. 12 A contains 60 inches in depth of sand of an effective size of 0.19 millimeter, and filters Nos. 15 B and 16 B contain 65 inches in depth of gravel stones of an effective size of 5.40 millimeters. Filter No. 12 A receives as much of the effluents of filters 15 B and 16 B as it is capable of disposing of, and, during 1896, its average rate of filtration has been 443,000 gallons per acre daily, with a maximum rate of 676,000 gallons in June. The quantitative capacity of the filter decreased during the first four months of the year. On April 9 the surface was spaded to a depth of 8 inches and during the greater part of May the filter was allowed to rest. During the following five months it was capable of receiving nearly the entire volume of the effluents of filters Nos. 15 B and 16 B. In November it again became clogged and was spaded over to a depth of 6 inches four times between November 14 and December 2, and upon

December 3 the upper foot of material was spaded over and thoroughly mixed.

Filters Nos. 15 B and 16 B were receiving sewage at the rate of 480,000 gallons per acre daily during the first months of the year. At this rate the filters became clogged and were allowed to rest with continuous aeration from May 1 to 11, inclusive. This air drawn through the filters at the rate of one gallon every four minutes improved the condition of the filters but slightly, and, beginning May 12, city water was applied to the filters in twelve applications daily and at a total rate of 120,000 gallons daily, the filter being aerated for eight hours each night. With this method of operation, which was continued for one week, the nitrogen stored in Filter No. 15 B was rapidly nitrified and removed as nitrates in solution, but Filter No. 16 B was so badly clogged that finally the entire filtering material had to be removed, washed and replaced. Since June 1 the filters have been operated at an average rate of 360,000 gallons per acre daily, and both were in good condition at the end of the year.

The following tables give the monthly averages of the analyses and the notes below the details of operation during the year:—

Effluent of Filter No. 12 A.

Sewage applied, 2 gallons seventy-two times a week, January 1 to May 11, except from March 18 to April 19 and May 1 to 11, when filter was allowed to rest; May 12 to 21, city water applied ½ gallon seventy-two times a week; May 22 to 30, sewage applied ½ gallon seventy-two times a week; June 1 to 7, 1 gallon applied seventy-two times a week; June 8 to 16, 2 gallons applied seventy-two times a week; June 17 to December 31, 1½ gallons seventy-two times a week, except from November 17 to 22, when filter was allowed to rest. March 1 to 10, experiment interrupted by freshet. Filter was aspirated eight hours each night except during periods of rest, when aspirator was run continuously. March 10, top 6 inches of gravel removed, washed and replaced. April 21 to July 21, trap removed during the day, and attached to faucet only while filter was being aspirated during the night. July 22, filter was emptled and washed out, and gravel washed and replaced. Surface raked 3 inches deep once each week. Surface spaded 12 inches deep on May 4 and 6 inches deep on November 17. May 2), filter flushed out with city water from below for one hour. Underdrains washed out with city pressure October 21 and December 16.

Filter No. 13 A.

This filter contains 60 inches in depth of medium fine sand of an effective size of 0.19 millimeter, and has received the supernatant liquid from sewage which has been allowed to settle for four hours. The average rate of filtration during 1896 has been 152,000 gallons per acre daily. The filter has been in good condition during the year, has disposed of the applied sewage readily and its effluent has been of a satisfactory quality.

The following table gives the monthly averages of the analyses and the notes below the details of operation of the filter:—

Effluent of Filler No. 13 A.

Settled sewage applied, 4 gallons twelve times a week. No sewage applied November 17 to 22. March 1 to 10 and April 17 to 20, experiment interrupted by freshet. Surface raked 3 inches deep twice each week. Surface dug over 8 inches deep April 9, and 6 inches deep on the following dates: June 27, August 1, November 17.

Filter No. 14 A.

This filter contains 60 inches in depth of medium fine sand of an effective size of 0.19 millimeter, and has received since June 1, 1894, sewage which has been first strained through a shallow layer of coke The average rate of filtration during 1896 has been 280,000 gallons per acre daily. This rate was too great, considering the strength of the applied sewage, and resulted in clogging the filter quite seriously towards the end of the year. From December 8 to 28, inclusive, city water was applied at the rate of 80,000 gallons per acre daily and considerable of the stored organic matter was removed.

The following table gives the monthly averages of the analyses and the notes below the details of operation of the filter: -

Four gallons of sewage strained through coke applied twenty-four times a week, January 1 to December 7; 1 gallon of city water twelve times a week, December 8 to 28; 4 gallons of sewage twentyfour times a week, December 29 to 31. No sewage applied February 19 to 23 and November 17 to 22. March 1 to 10 and April 17 to 20, experiment interrupted by freshet. Surface raked 3 inches deep twice each week. Surface dug over 8 inches deep, February 19, April 9, December 7, and 6 inches deep on the following dates: June 27, August 1, November 10 and 17.

Filter No. 19.

This filter contains 60 inches in depth of medium fine sand of an effective size of 0.19 millimeter, and has received the supernatant liquid from sewage which has been allowed to settle for four hours after treatment with sulphate of alumina at the rate of 1,000 pounds per 1,000,000 gallons. The filter has received this clarified sewage at an average rate of 190,000 gallons and has given a satisfactory effluent.

Sewage applied, 5 gallons twelve times a week, except from November 17 to 22, when filter was allowed to rest. March 1 to 10 and April 17 to 20, experiment interrupted by freshet. Surface raked 3 inches deep twice each week. Surface spaded over 8 inches deep on April 9, and 6 inches deep on June 27, August 1 and November 17.

Filter No. 21 A.

This filter contains 60 inches in depth of fine sifted gravel of an effective size of 1.60 millimeters. It was put in operation March 19, 1894, and since July 7 of the same year has had a current of air drawn downward through it at the rate of about one gallon in four minutes and for daily periods varying from ten to sixteen hours.

The prescribed rate of filtration has been 360,000 gallons per acre daily, and during 1896 the actual rate has been 344,000 gallons per acre daily. An exceedingly satisfactory effluent has been obtained, but the filter is gradually becoming clogged with organic matter, notwithstanding the aeration.

The following table gives the average analyses and the notes below the details of operation of the filter:—

Sewage applied, 1½ gallons seventy-two times a week, except from November 17 to 22, when filter was allowed to rest. Filter was aspirated sixteen hours each night, except during period of rest, when aspirator was run continuously. March 1 to 10 and April 18 to 20, experiment interrupted by freshet. Surface raked 3 inches deep once each week. March 10, 6 inches of gravel removed, washed and replaced. Surface spaded over 6 inches deep on June 27 and November 17.

Filter No. 22 A.

This filter contained 60 inches of fine coke breeze above the usual gravel underdrains and was constructed March 19, 1894. From that date until November, 1894, it received sewage at the rate of 240,000 gallons per acre daily, and from then until March, 1896, the average rate of filtration, excluding periods of rest, was 360,000 gallons per acre daily. During the freshet of the Merrimack River

at this latter date the filter was destroyed. During its period of operation the filter almost invariably gave an effluent containing considerable free ammonia but low in organic matter. The object of the experiment was to operate the filter at as high a rate as possible and obtain a satisfactory effluent, and remove clogged coke from the surface of the filter whenever necessary for the satisfactory working of the filter. During the experiment coke equivalent to 13.8 cubic yards per million gallons of sewage filtered was removed and when dried could be used as a fuel.

Filter No. 59.

This filter was one ten-thousandth of an acre in area and contained over the usual underdrains 60 inches in depth of gravel stones of an effective size of 2.50 millimeters. Down through the middle of the filter an iron pipe 1 inch in diameter was passed and this pipe reached to within 6 inches of the bottom of the filter. By means of this pipe and an aspirator, air was drawn through the filter. The filter was put in operation April 1, 1895, and sewage was applied to it at the rate of 500,000 gallons per acre daily up to Feb. 11, 1896. The results for 1895 are given in the report for that year. Upon February 11, wool-scouring liquor was mixed with the Lawrence sewage in such proportion that one-fifth the volume of the dose applied was wool liquor. The rate of filtration and the proportion of wool liquor in the sewage applied was reduced from time to time and the filter aerated for eight hours each night, but the effluent of the filter became of a very poor quality, the wool liquor passing through practically without change, and nitrification, which was active in the filter when this liquor was first applied, was entirely destroyed.

The following table shows the rate of filtration and the average analyses and the notes below give the details of operation:—

^{*} Brown.

Sewage applied, 54 gallons daily, six days a week, January 1 to February 10; sewage applied in the following manner: six doses of 5 gallons each applied in the forenoon, and six doses of 4 gallons each in the afternoon. February 11 to 13, 1 gallon of wool-scouring liquor and 4 gallons of sewage applied as one of the forenoon doses; February 14 to 23, 1 gallon of wool-scouring liquor in four doses of $\frac{1}{4}$ gallon each applied with regular sewage; February 24 to March 10, dose reduced to 25 gallons of sewage and 2 gallons of wool-scouring liquor, applied in nine doses of 3 gallons each; March 11 to May 16, dose reduced to 12\frac{1}{4} gallons of regular sewage and 2 gallons of wool-scouring liquor, applied in nine doses. Filter aspirated eight hours each night. March 1 to 10, experiment interrupted by freshet. March 10, the top 6 inches of gravel removed, washed and replaced. Surface raked 3 inches deep once each week.

Filter No. 65.

This filter contains, over the usual gravel underdrains, 60 inches in depth of coke breeze, and was put in operation Jan. 4, 1896. The sewage applied is that which has just been strained through a shallow layer of coke breeze (see page 479), and the average rate of filtration for the year has been 290,000 gallons per acre daily. The filter has disposed of the applied sewage easily and its effluent has been of a satisfactory quality.

The following table shows the average analyses of the effluent and the notes below give the details of operation of the filter:—

Five gallons of sewage strained through coke applied eighteen times a week. March 1 to 10, experiment interrupted by freshet. Surface raked 3 inches deep once each week, January 1 to May 25, and twice each week, May 26 to December 31. Surface dug over 6 inches deep on May 21.

Filters Nos. 66 and 67.

Filter No. 66 is one three-thousandth of an acre in area and contains 60 inches in depth of gravel of an effective size of 5.10 millimeters. The filter has a wooden bottom perforated with many holes, to allow the escape of the effluent freely without collection and passage through a single outlet, as is the case with the other filters. At the beginning of the experiment the two filters were connected by an airtight chamber and the effluent of Filter No. 66 passed directly upon the surface of Filter No. 67, placed below Filter No. 66.

Filter No. 67 is of one-half the area of Filter No. 66 and contains 60 inches in depth of sand of an effective size of 0.19 millimeter. A pressure pump capable, at its ordinary rate of operation, of pumping nineteen gallons of air per minute, was connected with the airtight chamber, and the air delivered into this chamber was forced up through the entire body of filtering material in Filter No. 66. This filter has been operated at rates varying from 90,000 to 513,000 gallons per acre daily, and with the amount of aeration given, as shown by the notes beyond, nitrification has been kept active. Owing, however, to the perforated bottom of the filter a considerable percentage of the sewage sludge has passed down through the filter instead of being stored within the filter.

Filter No. 67 has received, during a large portion of the year, the entire effluent of Filter No. 66, and has given a satisfactory effluent. This high rate of filtration has been maintained with considerable difficulty, owing to the amount of sludge in the effluent of Filter No. 66, and the clogged sand removed from Filter No. 67 has amounted to 22 cubic yards per million gallons of sewage filtered.

On November 7 the surface of Filter No. 66, with the exception of a circular opening 8 inches in diameter in the centre, was covered with 6 inches of coke breeze. The coke was for the purpose of straining out some of the sludge of the sewage, and the opening to allow the circulation of air when the filter was being aerated. The quality of the effluent was slightly improved by this change, but not enough to expect that the high rate of filtration through Filter No. 67 can be maintained without large removals of clogged sand from time to time or prolonged periods of resting.

The electric power to operate the aerating apparatus has been obtained from the Lawrence Gas Company, and, for the amount of

aeration given, the cost has been at the rate of several hundred dollars per million gallons of sewage filtered. With a larger plant, the cost would be less in proportion to the sewage filtered, but it seems improbable that it would be reduced sufficiently to be considered reasonable in sewage purification.

Effluent of Filter No. 66.

Effluent of Filter No. 66 applied: March 10 to June 30, all the effluent; July 1 to 12, one-half of the effluent in three doses of 25 gallons each; July 18 to 28, four doses of 25 gallons each; July 29 to September 6, four doses of 31\frac{1}{2} gallons each; September 7 to October 5, four doses of 18\frac{3}{2} gallons each; October 6 to November 10, four doses of 27\frac{1}{2} gallons each; November 11 to December 31, four doses of 50 gallons each. March 31 to April 17, surface raked 3 inches deep twice a week; April 18 to December 31, raked 3 inches deep daily. Surface dug over to a depth of 6 inches on the following dates: April 17; June 4, 6, 8, 11, 22, 29; July 1, 17; September 2; October 3, 10, 15, 19, 23, 26, 30; November 9, 12, 14, 16, 17, 23, 24, 25. June 27, filters 66 and 67 disconnected, and from 4 to 5 inches of sand removed from surface. November 26, 6 inches of sand removed.

Filters Nos. 80 and 81.

Filter No. 80 contains 4.5 feet in depth of coal ashes and has received sewage at the rate of 70,000 gallons per acre daily. Its effluent has been bright and clear from the beginning and in January of the present year (1897) nitrification began to be active.

Filter No. 81 contains 4.5 feet in depth of cinders and has received sewage which had first been strained through coke breeze at the rate of 550,000 gallons per acre daily. The method of operating the filter has been as follows: In the morning the outlet is closed and sewage is applied in hourly doses until the surface is covered; the filter is allowed to remain in this condition for two hours, when the outlet is opened and the filter slowly drained.

Effluent of Filter No. 80.

FILTRATION OF WATER.*

Seven of the experimental filters, used for the purpose of studying the purification of water by sand filtration during 1895 and previous years, have been continued in operation during 1896, and the results obtained by these filters, together with those obtained by three additional filters and the large filter 2.5 acres in area, constructed by the city of Lawrence and put in operation Sept. 20, 1893, are presented in the following pages. Reports of the Board for previous years have given facts and figures regarding the filtration of Merrimack River water through various depths and kinds and grades of sand, at various rates of filtration and with both continuous and intermittent filters. The data obtained and recorded in those reports are here added to, together with such new observations as seem to be especially worth recording.

Two distinctly new lines of investigation have been started: one, the study of the sand filtration of water much more polluted, both chemically and bacterially, than the Merrimack River water, and the other, studies in regard to the removal of iron in such forms as it exists in some of the water supplies of the State. The study of the purification of a highly polluted water has been carried on during a large portion of the year and considerable data can be given, but the study of the removal of iron was begun during the last part of the year.

The table on the following page shows the rate of filtration and the bacterial efficiency for the year of those filters receiving Merrimack River water. Determinations of the number of bacteria in the water applied to the filters are made twice each day, determinations of the bacteria in the effluents of filters Nos. 3B, 7A and 8A four times each day, and of the smaller filters always once and sometimes twice each day.

^{*} In preparing this paper the writer has had the assistance of Mr. W. R. Copeland.

DISCUSSION OF BACTERIAL EFFICIENCY OF THE FILTERS.

By a study of the table it is seen that all of the filters having an average depth of more than 12 inches of sand maintained an average bacterial efficiency of 99.24 per cent. or more. The greatest average efficiency, 99.70 per cent., was obtained by the large filter, No. 8 A, one two-hundredth of an acre in area, situated out of doors, containing 52 inches in depth of sand and operated continu-Filter No. 3B, of the same area and depth and also out of doors, but operated intermittently, gave an average bacterial efficiency of 99.54 per cent., but its average rate of filtration was much less than that of Filter No. 8A. An examination of the tables of daily results (see page 537 and following) shows that these large filters maintained a more uniform efficiency than the small filters, and that, of the large filters, the most uniform results were obtained by Filter No. 8 A. Nearly as uniform results were obtained by Filter No. 3B, and both filters gave a decidedly better day-by-day efficiency than the shallower or smaller filters.

Rates of Filtration and Bacterial Efficiency.

Filters Nos. 3B to 64, inclusive, have been operated at rates of filtration, in gallons per acre daily, varying from 1,960,000 on the part of Filter No. 33 A to 4,880,000 on the part of filters Nos. 43 and 62, and at these rates the bacterial efficiency obtained has been The efficiency has not borne a direct relation to the rate of filtration nor to the degree of coarseness or fineness of the sand. Filter No. 18 A, containing sand of an effective size of 0.48 millimeter and operating at the rate of 4,740,000 gallons per acre daily, has given an effluent containing on an average 47 bacteria per cubic centimeter, and Filter No. 33 A, containing sand of an effective size of 0.14 millimeter and operating at a rate of 1,960,000 gallons per acre daily, has given an effluent containing on an average 73 bacteria per cubic centimeter. It is true that Filter No. 18 A contained a greater depth of sand and that there was at times a growth of bacteria within the sand of Filter No. 33 A, as will be explained later, but the fact remains that the coarsest filter operating at the highest rate gave the best result. On the other hand, Filter No. 33 A could undoubtedly have been operated at a higher rate than it was operated and have given as good an effluent, while the rate of Filter No. 18 A if increased materially would probably have caused poor results to follow. Filter No. 33 A might even have given a better result at a higher rate, from the fact that the more rapid passage of the water through the filter would perhaps have diminished the number of those bacteria in the effluent which grew within the filter. (See page 525.)

The advantage of a filter of fine sand, such as Filter No. 33 A, over a filter of coarse sand is most marked at the beginning of its period of operation. The results then obtained are much better than obtained at the outset with coarse sand, but as the period of service of filters increases the efficiency of the coarse sand filters increases and the volume of water passed between scrapings is greater, other things being equal, with a filter of coarse sand. Better results immediately after scraping are, with the same treatment in each case, obtained by a filter of comparatively fine sand. These facts have been repeatedly stated in different reports of the Board, and tables given illustrative of them, and their repetition here is simply by way of explanation of the table given.

Remarks in Regard to Shallow and Deep Filters.

As noted in earlier reports of the Board, disturbing influences, such as scraping, fluctuations of rate of filtration, etc., affect more seriously the bacterial results obtained from shallow than from deep filters. It has also been noted that depth of water over the surface of a sand filter exerts a pressure upon the surface, rendering the upper sand layers so compact that the maximum rate, or quantitative capacity of the sand to the flow of water, is reduced. (See page 706, report of 1894.) Owing to this fact of pressure, of two filters containing the same total depth of sand and water, other things being equal, that one containing the greatest depth of sand and thus the least depth of water over its surface will require less frequent scraping than the one in which the relative depth of sand and water is reversed. It is also true that with the same depths of water over the surface of two filters containing different depths of sand the one containing the greatest depth of sand will require the least scraping. Filters Nos. 63 and 64, both filtering river water at a rate of 3,000,000 gallons per acre daily, and containing, from May 8 to July

28, an average depth of 22 and 9 inches of the same grade of sand respectively, have given results upon this point shown in the following table:—

Number of Scrapings, Water filtered between Scrapings, etc., with a Shallow as compared with a Deeper Filter.

| | Nu | IBER | of I | FILTE | R. | | Depth of Sand in Inches. | Average Depth of Water on Surface. | Number of Scrapings. | Number of Gallons filtered be- tween Scrapings (per Acre). | Average Rate of Fil- tration (Gallons per Acre Daily). |
|-----|----|------|------|-------|----|--|--------------------------------|---|----------------------------|---|--|
| 64, | | | | | | | 9 | 10 | 15 | 15,900,000 | 2,900,000 |
| 63, | | | | | | | 22 | 10 | 12 | 20,560,000 | 3,000,000 |

On July 28 the head on Filter No. 64 was reduced so that the depth of water on the surface compared to the depth of sand should correspond more nearly with the ratio of the depth of water to depth of sand in Filter No. 63.

The results obtained from filters Nos. 63 and 64, covering the period May 18 to October 31, together with results from the larger filters, Nos. 7 A and 8 A, have been gathered together in the following table. Filter No. 7 A had not been in operation for the four months just previous to this period and its surface was therefore very porous, but as Filter No. 8 A had been scraped and dug over 6 inches deep on April 11, the surface layers of 7 A and 8 A were probably about equally porous when the experiment started.

Table showing the Number of Scrapings, Cubic Yards of Sand removed, etc., in operating Shallow as compared with Deeper Filters.

| NUMBER OF FILTER. | Period. | Average Depth of Sand (Inches). | Number of Scrapings. | Actual Number of Gallons filtered. | Cubic Yards of Sand removed per Million Gallons filtered. | Average Bacterial Efficiency. |
|----------------------|---------------------|--|----------------------------|---|---|-------------------------------------|
| 7A, | Apr. 13 to Dec. 31, | 13 | 14 | 4,825,165 | 0.98 | 99.25 |
| 8 A, | Apr. 13 to Dec. 31, | 48 | 11 | 5,214,181 | 0.67 | 99.71 |
| 64, | May 18 to Oct. 31, | 7 | 29 | 24,210* | - | 98.16 |
| 63, | May 18 to Oct. 31, | 21 | 21 | 24,607* | - | 99.41 |

^{*} Filters Nos. 63 and 64 are only one-hundredth the area of filters Nos. 7 A and 8 A.

From this table it is evident that the shallow filters Nos. 7 A and 64 were scraped more frequently, that the number of cubic yards of

sand scraped off per million gallons of water filtered was greater, and that the average bacterial efficiency was less than of the deeper filters Nos. 8 A and 63. The table is significant owing to the fact that one of the largest items in the cost of running sand filters is caused by scraping sand from the filter and replacing it with new.

Effect of Spading the Surface Layers of Deep and Shallow Filters.

It has been stated in the present report, and considerable data upon the subject have been given in previous reports, that shallow filters are much more sensitive to disturbing influences than deeper ones. That is to say, when the surface deposit is removed or the surface spaded over, that a filter containing a considerable depth of sand will produce a better bacterial efficiency immediately afterwards than one containing a shallower depth of sand.

The two following tables illustrate this point: -

Effect produced upon Bacterial Efficiency by Spading a Shallow Filter.

Note. — The number of bacteria in the canal water applied to Filter No. 8 Λ on December 3 averaged 4,800 per cubic centimeter.

Both of these filters were spaded over 6 inches deep and after spading were filled slowly with city water from below and allowed to stand for twenty-four hours. On the days when the outlet valves were again opened Filter No. 7 A ran at a rate of 5,034,000 gallons per acre daily, but Filter No. 8 A fell a little short of this, running at a rate of 4,390,000 gallons. This rate gradually increased until it reached 5,000,000 gallons, and maintained an average rate of 5,180,000 gallons per acre daily from December 5 to 10.

The difference in rate between 4,300,000 and 5,000,000 gallons per acre daily was not sufficient to account for the great difference between the numbers of bacteria which were found in the effluents of filters Nos. 8 A and 7 A on the first day after the outlets were opened. For instance, the number of bacteria found in the effluent from Filter No. 8 A averaged 9 per cubic centimeter, whereas the number found in the effluent from Filter No. 7 A averaged 1,984 per cubic centimeter. The mechanical disturbance of spading affected Filter No. 8 A to some extent however, and the bacterial efficiency

decreased together with the increase in rate during the period from December 4 to 10. Thus the figures given in the table show that, whereas on December 3 the bacteria in the effluent of Filter No. 8 A averaged 9 per cubic centimeter, during the period from December 4 to 10 the bacteria averaged 274 per cubic centimeter.

REMARKS IN REGARD TO INTERMITTENT AND CONTINUOUS FILTRA-

For six years filters receiving Merrimack River water and operated continuously and intermittently have been studied at this station. The first experimental water filter, No. 8, was put into operation in November, 1887, and continued until September, 1893. This filter contained, above the usual underdrains, 3 feet and 8 inches in depth of a mixture of gravel and sand of an effective size of 0.35 millimeter; above this layer were 8 inches of yellow loam, and above this a layer 6 inches deep of the same kind of material as that which lay below the loam.

City water was applied to this filter at rates varying from 100,000 to 300,000 gallons per acre daily, and the effluent was a clear, bright, almost colorless water with a taste like that of spring water. On Nov. 13, 1891, Merrimack River water, taken from the Essex Company's canal, began to be applied to this filter at the rate of 300,000 gallons per acre daily, instead of the city water previously applied. The river water contained many times as many bacteria per cubic centimeter and more organic matter than the city water previously applied, which, although taken from the river in the first place, had passed through the reservoir and city service pipes before reaching the station. The effluent of the filter, however, continued as pure chemically and with no more bacteria than when city water was applied. The average removal was 99.97 per cent. and the few bacteria appearing in the effluent were believed to be due to growths in the underdrains.

Thus the effluent of this filter was in every way satisfactory, but owing to the layer of loam it was impossible to increase the rate of filtration above 300,000 gallons per acre daily; and, as this loam began to clog with the organic matter removed from the water, this quantitative capacity decreased and the filter was discontinued in 1893, as before stated.

In the meantime other filters were put in operation, some of sand with layers of loam and others with their entire depth above the

underdrains consisting of one grade of sand, and at the close of 1892, eighteen water filters either were or had been in operation at the station, ten continuous and eight intermittent filters, and in the report for that year a comparison of results obtained by the two methods of filtration was given and the statements made that:—

- 1. In continuous and intermittent filtration through materials of the sizes employed and at the given rates there is no very great difference in the amount of organic matter removed from the applied water.
- 2. Continuous filters require scraping less frequently than intermittent.
- 3. It will be necessary to obtain more data before making definite conclusions in regard to the bacterial efficiency of the two methods.

During this year the rates of filtration of the different filters varied from a few hundred thousand to two million gallons per acre daily. During 1893 the number of experimental filters was added to and the rates of filtration in gallons per acre daily increased, so that several filters were operated at the rate of between three and five million gallons per acre daily and the comparative results obtained from the continuous and intermittent filters were summarized as follows:—

- 1. That in the case of the filters of fine sand, in which there is a saturated layer of considerable depth, the bacterial efficiency was substantially the same by each method employed in the application of water during the greater part of the year, but during midsummer (July 24 to September 2) the continuous filters allowed a few more of the hardy water bacteria, but not of *B. prodigiosus*, to pass through.
- 2. That with filters of coarser sands, operated at comparatively high rates, the continuous filters are ordinarily more efficient in removing bacteria than the intermittent filters under the existing methods of operation. The reason of this is that the actual rate of flow was lower and more uniform and there was no mechanical disturbance of the sand, as was the case during the greater part of the period with the intermittent filters, owing to the manner of filling and driving out the air.

During 1894, 1895 and 1896 intermittent and continuous filters were continued in operation, and the results obtained from all of them have been important and instructive, but the most important

have undoubtedly been obtained by filters Nos. 3 B and 8 A. These two filters were put in operation in September, 1893, and from the day when first flooded up to the present time have been running without interruptions, except those caused by scraping or other necessary details of operation. These two filters are each one two-hundredth of an acre in area and their location is such as to make them comparable with large filters of a city supply system. They each have the same depth of the same grade of sand and have been operated at rates varying from 2,000,000 to 5,000,000 gallons per acre daily. Filter No. 3 B has always been operated intermittently while Filter No. 8 A has been operated continuously, and the following table gives the average rate of filtration and the average bacterial efficiency of each filter for each year of operation:—

| | Fı | LTER | NUM | BER. | | | | | | Year | | | | Rate. | Bacterial Efficiency |
|--------------|----|------|-----|------|---|---|---|--------|---|------|---|---|-----|------------------------|-------------------------|
| 3 B, 8 A, | • | | • | | • | | • | 1893,* | | • | | | . } | 2,095,000 | 95.60 97.80 |
| B B, | | | | | | | |) 1004 | | | | | (| 2,932,000 | 99.16 |
| 3 А, | • | • | ٠ | • | • | ٠ | | 1894, | ٠ | ٠ | ٠ | • | * { | 3,107,000 | 99.22 |
| B B, | | | | | | | | 1895, | ٠ | | | | . { | 3,096,000 3,576,000 | 99.16 99.73 |
| В, | | | • | | | | |) | | | | | | 2,868,000 | 99.54 |
| Α, | | | | | | | | 1896, | ٠ | ٠ | ٠ | ٠ | . { | 3,694,000 | 99.70 |

* Three months only.

The table shows that Filter No. 8 A has been operated at a higher rate of filtration than Filter No. 3 B, although it can be stated here that it has been the intention to have the two filters operating at equal rates. (The explanation of the difference in rate of flow is given on page 516 and following.) The table also shows that the bacterial efficiency of Filter No. 8 A has always averaged greater than that of Filter No. 3 B, and it can be stated here, and an examination of the tables of daily results given in the various reports will show, that its uniform efficiency has also been greater.

The reason that continuous filtration has been so entirely successful is the fact that the river water always contains dissolved oxygen in such quantities that the effluents of the continuous filters always

contain it, except in midsummer, when with filters of fine sand its entire or almost entire absence has been noted on several occasions. The effluents of filters constructed of sand as coarse as that of filters Nos. 3 B and 8 A have never shown an entire absence of oxygen.

Filters Nos. 3 B and 8 A, one two-hundredth of an Acre in Area.

The Quantitative Capacity of the Intermittent and Continuous Filters Nos. 3B and 8A.

The table on page 507 shows that the average rates of filtration for filters Nos. 3B and 8A were, respectively, 2,868,000 and 3,964,000 gallons per acre daily. The whole number of gallons filtered during the year was 4,645,440 gallons for 3 B and 5,984,107 for 8 A, or 3 B filtered 1,339,000 gallons less than 8A, although the intention was to have the same number of gallons pass through each filter every day. To do this, of course, the rate of filtration of 3 B would necessarily be greater, during a portion of the day, than the rate of 8 A, in order to make up for that period of the day when the surface of 3B was uncovered and the filter simply draining. It was impossible, however, with Filter No. 8A operating at the rate given, to equalize the flow for the following reason: the surface of 3B stands uncovered for two hours each day and, as the water gradually sinks away from the surface, air presses in to fill up the interstices between the grains of sand. When water is again turned on to the filter the air held in the sand works its way to the surface, or is forced downward and out through the underdrains. water carries considerable fine material in suspension, and this is strained out at the surface and in the open spaces in the upper layers

of sand so that the channels by which the air can escape easily are soon filled. No longer having an easy chance of escape, the air which is retained in the filter fills up the open spaces and increases the frictional resistance to the passage of water through the sand. Since the water works its way more slowly each day through the filter, owing to increased clogging, it takes a longer time each day for the intermittent filter to uncover and also for it to return to its maximum rate of flow. The more slowly the rate increases, the smaller the amount of water filtered will be each succeeding twenty-four hours. Owing largely to the presence of air in the filter, therefore, the quantity of water filtered through 3 B has been less than through 8 A.

Comparison of the Quantitative Efficiency of Intermittent and Continuous Filters, 3 B and 8 A, at Different Seasons of the Year.

| | | | | 3 B | (INTERMITTE | NT). | 8.4 | (CONTINUOU | s). |
|---------|------|-----|------|--|--|---|--|--|--|
| Seaso | N OF | THE | Yrar | Average Temperature of Effluent (Degrees F.). | Average Number of Days elapsed be- tween Scrapings. | Average Number of Gallons passed be- tween Scrapings (per Acre Daily). | Average Temperature of Effluent (Degrees F.). | Average Number of Days elapsed be- tween Scrapings. | Average Number of Gallons passed be- tween Scrapings (per Acre Daily). |
| Warm, . | | | • | 69 | 17 | 3,558,000 | 71 | 17 | 4,467,000 |
| Cold, . | | | | 43 | 11 | 3,271,000 | 42 | 25 | 4,623,000 |

The table also shows that Filter No. 8 A was scraped much oftener in summer than in winter, but this low summer average of seventeen days between scrapings was partly due to the fact that the surface of this continuous filter became covered several times during the summer with a thick mat-like growth of *spirogyra* which had to be removed. Omitting the scrapings from this cause the average number of days elapsing between scrapings would be greater.

One reason why the winter average of days elapsing between scrapings is so great is that on December 1 the filter was spaded over to the depth of 6 inches.

Air dissolved in the Water and its Physical Action in Filtration.

The canal water always contains some dissolved oxygen; the amount varies with the temperature and is greater in cold than in warm water. During summer weather the canal water is warm and contains a small amount of dissolved oxygen; but as this water

penetrates the filter it becomes colder, because the temperature within the filter is lower than that of the water or outside air and for this reason it absorbs some of the air held in the sand. Hence during warm weather the water in passing through the filter reduces the amount of air held in the sand and thus decreases the frictional resistance of the filter to the flow of water. On the other hand, during cold weather the water when applied to the filter is generally nearly or quite saturated with dissolved oxygen and gives up part of it as it passes down through the warmer bed of sand. In cold weather, therefore, while passing through the filter the water increases the amount of air held in the sand and as a result the frictional resistance of the filter to the passage of water is increased. It is also true that the viscosity of cold water is greater than that of warm water and a given amount of frictional resistance in a filter will retard the flow of water in winter more than it will in summer.

Continuous filters are affected less in this respect by the change of temperature in winter, because the surface of the filter remains covered and the air set free from the water as it passes through the filter, and held in the sand, is not added to by air introduced by surface exposure. As a result, the frictional resistance to the passage of water is less than in an intermittent filter and the period between scrapings is longer. These conclusions are of the filtration of water of about the character of that of the Merrimack River.

Removing Air from Filters by allowing them to stand with Outlets closed for Twenty-four Hours.

It has been found that, when air has accumulated in the pores of a continuous filter to such an extent that it interferes with and decreases the rate of filtration, allowing the filter to stand inoperative for twenty-four hours, with its surface covered with water, expels, absorbs or exhausts the air, and on again starting filtration the frictional resistance of the filter to the passage of water has decreased and the desired rate of filtration can be continued for a considerable period without the necessity of scraping. The following record illustrates this point.

The prescribed rate of Filter No. 8 A is 5,000,000 gallons per acre daily, and, as this filter is one two-hundredth of an acre in area, to maintain this rate it is necessary to filter 25,000 gallons of water each twenty-four hours. As before stated, an effort is made to operate Filter No. 3 B at the same rate.

Both filters were scraped on a certain day in the usual manner, the water first being drained from them sufficiently to allow the surface to be walked upon. This draining of course allowed air to enter each filter, a daily occurrence with 3 B but unusual with 8 A and occurring only at times of scraping. Both filters were then filled slowly from below with city water and allowed to stand for twentyfour hours with their surfaces covered with water. On putting both filters into operation again, Filter No. 8 A allowed only 14,738 gallons to pass through it in the first twenty-four hours of operation, although the outlet valve was wide open. This total flow increased daily owing to the absorption or expulsion of the air from the filter, until on the fourth day it was 21,004 gallons, where it remained for several days. Filter No. 3 B, on the other hand, on being put into operation after scraping, allowed 29,351 gallons of water to flow through it on the first day and this rate decreased daily until on the fourth day, with the outlet valve wide open, the total flow was only 22,000 gallons. This being the usual action of these two filters after being scraped.

After Filter No. 3 B had been in operation four days following scraping and Filter No. 8 A seven days, both filters were allowed to stand inoperative for twenty-four hours with their surfaces covered with water. Following this treatment it was possible to maintain the desired rate of flow through Filter No. 8 A for seven days. With Filter No. 3 B, however, only on the day following standing closed did the volume of effluent approximate 25,000 gallons, and on this day the filter was operating continuously.

Summarizing, it can be said that when Filter No. 8 A is scraped to remove clogging and air allowed to enter it, on again starting filtration, other things being equal, its rate of flow is low at first but increases day by day for several days. When Filter No. 3 B is treated in a like manner its rate of flow is greatest on the day following such treatment and decreases daily.

Allowing both filters to stand inoperative for twenty-four hours has a more permanent effect upon the rate of Filter No. 8 A than upon the rate of Filter No. 3 B.

Table showing the Effect of closing the Outlet of Intermittent and Continuous Filters, Nos. 3 B and 8 A, for Twenty-four Hours, at Different Seasons.

| 3B, | | | | 68 | 3,878,000 | 3,641,000 | 40 | 3,348,000 | 2,958,000 |
| 8 A, | | | | 74 | 4,960,000 | 4,405,000 | 39 | 3,081,000 | 3,395,000 |

This table shows that by allowing continuous Filter No. 8A to stand closed for twenty-four hours in cold weather, the average daily flow increased from 3,081,000 gallons per acre daily to 3,395,000 gallons per acre daily, an increase of 314,000 gallons. In warm weather, on the other hand, the average daily flow fell off from 4,960,000 gallons per acre daily to 4,405,000 gallons per acre daily. a decrease of 555,000 gallons. The reasons why the flow increased in cold weather has already been explained. Turning to the figures for intermittent Filter No. 3 B we find that the quantitative capacity fell off, in warm weather, from 3,878,000 gallons per acre daily to 3,641,000 gallons, or 6 per cent., and in cold weather from 3,348,-000 gallons per acre daily to 2,958,000 gallons, or 11 per cent. From this we may infer that standing closed produced less effect in cold than in warm weather. The reasons for this are found in the facts, as stated on page 517, that a greater quantity of air collects in the sand in cold weather, and also because the viscosity of the water is greater in cold weather. These two factors combine to increase the frictional resistance to the passage of water through the sand and reduce the quantitative capacity of the filter.

The mechanical disturbance caused by spading the surface has already been referred to in connection with the decrease in bacterial efficiency which follows scraping, and it has been shown on page 519 that the quantitative efficiency of an intermittent filter is greater than that of a continuous filter on the few days which immediately follow a scraping. It is interesting to note in this connection the average number of bacteria in the effluents of filters Nos. 3 B and 8 A on the days after a scraping in 1896.

Average Number of Bacteria in the Effluents of Fillers Nos. 3 B and 8 A for the Three Days following Scraping, 1896.

| | | | Nu | BER | of F | LTE | R. | | | | Whole Number of Times scraped. | Average Number of Bacteria per Cubic Centimeter in Effluent, |
|------|--|---|----|-----|------|-----|----|---|--|---|-----------------------------------|--|
| 3 B, | | | | | | | | • | | | 20 | 88 |
| 8 A, | | • | | ٠ | | | ٠ | | | • | 15 | 27 |

This table shows that the number of bacteria per cubic centimeter was greater in the effluent from intermittent Filter No. 3 B than in the effluent from continuous Filter No. 8 A. We may therefore infer that scraping produced the most marked effect on the bacterial efficiency of the intermittent filter, but it must also be remembered that the rate of filtration of Filter No. 3 B has been greater immediately after scraping than the rate of Filter No. 8 A.

Intermittent and Continuous Filtration of Water more polluted than Merrimack River Water.

The water of the Merrimack River, while seriously polluted by the large volume of sewage flowing into it from the cities and towns on its watershed above Lawrence, and unsafe for domestic purposes without filtration because this sewage pollution brings disease germs into it, does not, as it flows by Lawrence, contain enough organic matter to prevent the presence in it of oxygen at all seasons of the year. The presence of this dissolved oxygen is the reason that continuous filtration of this water is successful.

During the past year two filters, containing 5 feet in depth of sand of an effective size of 0.23 millimeter, have been in operation, re-

ceiving water more seriously polluted than that of the river and hence containing less dissolved oxygen. The water applied to these filters is river water to which a certain proportion of sewage was added and then the mixture allowed to stand for a period before flowing upon the filters. This period of standing was for the purpose of exhausting more of the oxygen of the river water than would have been exhausted if the mixture had been applied directly to the filters. One of the filters was operated continuously and the other one intermittently.

Average Analysis of the Water applied to Filters Nos. 68 and 69.

[Parts per 100,000.]

| | Амм | ONIA. | | NITRO | GEN AS | | |
|--------|-------|-------------|-----------|-----------|-----------|---------------------|--------------------------------------|
| Color. | Free. | Albuminoid. | Chlorine. | Nitrates. | Nitrites. | Oxygen Consumed. | Bacteria per Cubic Centimeter. |
| .47 | .1958 | .0432 | . 64 | .025 | .0014 | .46 | 186,000 |

An examination of this table shows that the water applied to these two filters has contained eleven times as much free ammonia, two and one-half times as much organic matter determined as albuminoid ammonia, and twenty-four times as many bacteria per cubic centimeter as the river water. (See table, page 532.) In regard to the oxygen dissolved in the water, it can be stated that it averaged much less than that in the river water and was much more variable in amount from day to day, but was never found to be entirely absent in the water when applied to these two filters, except upon one occasion. filters were put in operation May 19 at the rate of 5,000,000 gallons per acre daily; this rate was reduced May 25 to 2,500,000 gallons per acre daily, and on August 20 to 1,000,000 gallons per acre daily and continued at this rate for the remainder of the year. As stated before, Filter No. 68 was operated continuously and Filter No. 69 intermittently. Dissolved oxygen was always present in the effluent of Filter No. 69 while it was not found in the effluent of Filter No. 68 on numerous occasions during the warm weather. The average amount - percentage of saturation - found up to December 31, in the effluent of Filter No. 68, was 8.70, and in the effluent of Filter No. 69, 43.30. During the first two months of operation both filters gave effluents containing high numbers of bacteria and showing only a small reduction of the organic matter of the applied water. During the remainder of the year much better results were obtained from both filters but especially from intermittent Filter No. 69.

Average Monthly and Yearly Bacterial Efficiency of Filters Nos. 68 and 69.

[May to December, inclusive, 1896.]

| 27- | | | | | | Av | ERAGE I | PER CEN | T. OF B | ACTERIA | REMOV | ED — | |
|-----|----------------------|---|---|-------------------------|-------|-------|---------|---------|---------|---------|-------|-------|----------|
| | NUMBER OF FILTER. | | | Method of Operation. | May. | June. | July. | Aug. | Sept. | Oct. | Nov. | Dec. | Average. |
| 68, | | | | Continuous, . | 49.30 | 14.83 | 87.72 | 90.75 | 95.53 | 97.02 | 96.03 | 98.43 | 76.89 |
| 69, | | • | ٠ | Intermittent, . | 80.00 | 73.70 | 93.25 | 99.10 | 98.53 | 99.49 | 99.34 | 99.88 | 91.80 |

During December the average daily number of bacteria found in the effluent of Filter No. 68 was more than 2,000, while in Filter No. 69 it was less than 200, and it is apparent from this table that the filters improved in bacterial efficiency steadily from May to December. It is also apparent that the intermittent filter improved faster and obtained a higher degree of efficiency than the continuous Filter No. 68.

The average rate of filtration was about the same, but in order to maintain the rate, Filter No. 69 was scraped more frequently than Filter No. 68, on account of the frictional resistance to the flow of water caused by the gelatinous organic matter left in the surface layers of the sand by this highly polluted water and its power to hold the air introduced by the surface exposure of this intermittent filter. It is probable that raking the filter would have been as effective in many instances as scraping, and of course more economical.

The chemical purification of the applied water that was effected by these two filters is shown by the following table:—

Effluent of Filters Nos. 68 and 69.

[Parts per 100,000.]

| _ | | | | | | Average | | Аим | ONIA. | | Nitro | GEN AS | med. |

For further details in regard to these filters see pages 558 to 564.

Double Filtration of Highly Polluted Waters.

By the filtration of a highly polluted water through filters Nos. 68 and 69, a considerable degree of purification has been obtained. This is especially true of the results obtained by intermittent Filter No. 69, which towards the end of the year produced an effluent not only quite pure chemically but with comparatively low numbers of Whether a water of the character of that applied to these filters would, with the purification obtained by Filter No. 69 towards the end of the year, be a safe water for domestic purposes is a subject of considerable importance, but not one upon which much data can be given at the present time. A study of the degree of purification to be obtained by a second filtration of this water, that is, a filtration of the effluent of filters Nos. 68 and 69, was begun September 18. A filter containing 5 feet in depth of sand of an effective size of 0.23 millimeter was put in operation, receiving the combined effluents at the rate of 5,000,000 gallons per acre daily. This applied water stood in a wooden collecting basin before going to the filter, and the number of bacteria increased either by growth or contamination, so that, as applied to the filter, its bacterial contents were somewhat higher than when flowing from filters Nos. 68 and 69. This last filter was designated Filter No. 79, and during the first two months of operation its bacterial efficiency was low, being only 54.10 per cent., due, in part, it is now believed, to the passage of a small percentage of the water down the side of the filter, and

not through the sand. At any rate, when this was suspected and the filter reconstructed upon November 20, the bacterial efficiency of the filter became slightly higher.

The main cause of the low efficiency, however, was undoubtedly due to the fact that the water applied to the filter had already passed through the 5 feet of sand in either Filter No. 68 or No. 69 and been largely relieved of that organic matter originally present in it which is deposited upon the sand grains and forms the gelatinous coating so important in producing satisfactory bacterial results. It will be remembered in this connection that in the report of the Board for 1894, pages 586 to 589, inclusive, results obtained by applying Lawrence city (filtered) water to five sand filters are given and discussed. In this experiment the filters used had all been in operation filtering river water during the previous year, and although they had remained out of operation for a period of several months immediately preceding the application to them of this filtered water, yet their sand grains held a considerable coating of organic matter, as shown by the tables on pages 602-604, in the same report. Notwithstanding this fact, however, "it was not until their fourth week of operation that the number of bacteria in any of the effluents became as low as that in the city water applied," and the decrease after this period was very gradual.

With Filter No. 79, then, constructed of clean sand almost entirely free from organic matter, it is not surprising that even a longer period has been required to obtain a condition of the sand capable of giving satisfactory bacterial efficiency, even though the filtered water applied has not averaged so free from organic matter as the city filtered water applied to the filters in 1894 in the experiment referred to.

If a water containing more organic matter had been applied to Filter No. 79, a shorter period of low efficiency would have resulted, because the sand grains would have become more quickly covered with this organic matter.

Increased Numbers of Bacteria found in the Effluents of Filters after standing closed for Twenty-four Hours.

Bacterial analyses show that the number of bacteria in the effluent from the water filters increased when the filters stood inoperative for twenty-four hours. In order to make repairs the water was drawn out from the Essex Company's canal frequently during the year, and at such times the outlets of the water filters were shut and the filters allowed to stand with their surfaces covered with water. Unusually great numbers of bacteria were found in some of their effluents when they were again put into operation.

Average Number of Bacteria per Cubic Centimeter in the Effluents from the Water Filters before and after standing closed.

| | | | | | | | FILTE | RS NUMB | ers- | | | |
|--------------|---|---|---|------|------|------|-------|---------|------|-----|-----|-----|
| | | | | 3 B. | 7 A. | 8 A. | 18. | 33. | 43. | 62. | 63. | 64. |
| Day before, | | | | 24 | 59 | 16 | 42 | 49 | 32 | 47 | 31 | 90 |
| Day after, . | • | • | ٠ | 24 | 127 | 39 | 102 | 681 | 153 | 174 | 124 | 313 |

From this table it is apparent that intermittent Filter No. 3 B was less affected than its continuous mate, Filter No. 8 A. It is also apparent that the continuous Filter No. 33, constructed of fine sand and operated at a low rate, was affected in a greater degree than were any of the other filters. It is also true that the water which passed through it was deprived of its dissolved oxygen to a greater degree than in the instance of the other filters, because the slow rate of filtration and the compactness of the sand gave a great opportunity for the organic matter in the sand to combine with the oxygen carried in the water.

Average Per Cent. of Saturation of Dissolved Oxygen in the Effluents from the Water Filters, 1896.

| | | | F | LTERS N | CMBERS - | - | | |
|--------------------------|-------------|------|------|---------|----------|-----|-----|-----|
| | 3 B. | 7 A. | 8 A. | 33. | 43. | 62. | 63. | 64. |
| Per cent. of saturation, | 84 | 58 | 67 | 40 | 71 | 45 | 51 | 56 |

In this table the average per cent. of saturation of the effluent of Filter No. 33 is given as 40, but as an actual matter of fact the effluent from Filter No. 33 often contained less than 1 per cent. of the oxygen necessary for saturation.

When the filters were put into operation after standing inoperative, analyses of the effluents collected at different hours showed that the number of bacteria per cubic centimeter was greater in the first portion of the effluent than in the portion of the effluent which issued after the filter had been in operation for several hours. This is well shown in the following table:—

Number of Bacteria per Cubic Centimeter in the Effluent from Filters Nos. 8 A, 33 and 43, after standing closed for Twenty-four Hours, Nov. 15, 1896.

| | | | | | | | In Samples | COLLECTE | D AFTER TE | IE VALVE H | AD BEEN O | PEN FOR- |
|------|---|-------|------|------|----|--|------------|----------|------------|------------|-----------|----------|
| | 1 | FILTE | B NU | MREF | 3. | | 5 Minutes. | 1 Hour. | 2 Hours. | 4 Hours. | 6 Hours. | 8 Hours. |
| 8 A, | | | | | | | 11 | 16 | 13 | 21 | 13 | 15 |
| 33, | | | | | | | 82 | 235 | 216 | 113 | 98 | 44 |
| 43, | | | | | ٠ | | 528 | 149 | 96 | 117 | 112 | 100 |

These samples were collected in November, when the applied water was nearly saturated with dissolved oxygen and the dissolved oxygen in the effluent from Filter No. 33, for the month, averaged 80 per cent. of that necessary for saturation.

After Filter No. 33 A had stood closed for several hours, in warm weather, the effluent often contained great numbers of bacteria, as shown in the following table:—

Number of Bacteria per Cubic Centimeter in the Effluent from Filter No. 33 A, on Sept 21, 1896.*

| | In Samp | LES COLLECTED | AFTER THE VAL | VE HAD BEEN C | PEN FOR- | |
|------------|---------|---------------|---------------|---------------|----------|-----------|
| 5 Minutes. | 1 Hour. | 2 Hours. | 4 Hours. | 6 Hours. | 8 Hours. | 24 Hours. |
| 1,608 | 1,245 | 1,143 | 1,040 | 632 | 558 | 118 |

^{*} The filter stood closed over Sunday, September 20.

The high numbers of bacteria found in the effluent might have been due to several causes. For instance, the bacteria might have grown on the organic matter in the sand, or the mechanical disturbance made by opening the valve suddenly might have formed channels through the sand, or the bacteria which were present in the water before closing might have multiplied gradually.

In order to determine which of these factors was the probable cause of the high numbers, city water was applied to Filter No. 33 on September 25 and 26. Up to September 24 canal water had been applied to Filter No. 33, and city water was now applied because it contained certain characteristic and easily identified species of bacteria. After the filter had become seeded with these

species they ought to have multiplied abundantly if the increase was due to the fact that the bacteria fed on the organic matter in the sand. Analyses showed, however, that the majority of the bacteria, forming the high numbers in the effluent, did not belong to the species which were characteristic of the city water.

When the filter was put into operation again on September 28, after standing closed for twenty-four hours, canal water was applied as usual, and if any channels had been formed in the sand, the number of bacteria in the effluent ought to have been greatest when the canal water first worked its way through the filter. The applied water required about eight hours to pass through the sand, and as a matter of fact the numbers of bacteria had begun to decrease by that time, as shown in the following table:—

Number of Bacteria per Cubic Centimeter in the Effluent from Filter No. 33 A, on Sept. 28, 1896.

| | | Ar | TER THE VAL | LVE HAD BEI | en Open for | R — | | |
|------------|---------|----------|-------------|-------------|-------------|----------|-----------|-----------|
| 5 Minutes. | 1 Hour. | 2 Hours. | 4 Hours. | 5 Hours. | 6 Hours. | 8 Hours. | 10 Hours. | 24 Hours. |
| 2,394 | 2,646 | 2,145 | 3,696 | 6,072 | 2,898 | 1,932 | 1,071 | 372 |

This table shows the numbers of bacteria found in the effluent increased from the first to the fifth hour and then decreased steadily. It is evident, therefore, that the high numbers were not due to the presence of canal water, which had been purified only partially in its passage through the sand. Experiments made on other days showed that the number of bacteria found in the effluent decreased steadily from the time when the valve was first opened. This is well illustrated by the table on page 527.

In order to make a more complete test for channels through the sand, a pure culture of B. prodigiosus was added to the applied water on September 26 and 28, but the organism was found in only two samples of the effluent. Had there been any channels through the sand it would have appeared in greater numbers.

The bacteria which were most common in the effluent belonged to a single species, as is shown in the following table, giving the number of bacteria which belonged to each of the four species found most frequently in the effluent from Filter No. 33 A on Sept. 28, 1896:—

No. 34.]

| Bacteria per Cubic Centimeter belonging to the Different Species | |
|--|-----|
| | 1.7 |

| IN SAMP | LE (| COLLE | CTED | AFT | ER V | ALVE | HAD | BEE | OPI | EN- | Species No. 3. | Species No 5. | Species No. 6. | Species No. 7. |
|------------|------|-------|------|-----|------|------|-----|-----|-----|-----|-------------------|------------------|-------------------|-------------------|
| 5 minutes, | | | | | | | | | | | 0 | 7 | 2,200 | 187 |
| 1 hour, . | | | | | | | | | | | 0 | 12 | 2,400 | 223 |
| 2 hours, | | | | | | | | | | | 17 | 0 | 2,000 | 128 |
| 4 hours, | | | | | | | | | | | 6 | 6 | 3,300 | 349 |
| 5 hours, | | | | | | | | | | | 10 | 10 | 5,500 | 535 |
| 6 hours, | | | | | | | | | | | 32 | 9 | 2,572 | 250 |
| 8 hours, | | | | | | | | | | | 18 | 4 | 1,900 | 10 |
| 0 hours, | | | | | | | | | | | 7 | 8 | 1,051 | 4 |
| 4 hours, | | | | | | | | | | | 6 | 56 | 154 | 0 |

This table indicates that an average of about 65 per cent. of the bacteria found in the effluent belonged to species No. 6, one of the class of bacteria which is known as Facultative Anaërobes, or bacteria which can grow without access to air. Attention has already been called to the fact that this species was especially prevalent in the portion of the effluent which issued during the first six hours, when the water contained the smallest amount of dissolved oxygen.

These bacteria appeared in the effluents from the various other filters, but in smaller numbers.

The results of the foregoing experiments and analyses indicate that the high numbers of bacteria, which appeared in the effluents from filters after they had stood closed for twenty-four hours, were not due to a growth of many kinds of bacteria on the organic matter in the sand, nor to channels in the sand made by throwing the valve open suddenly, but were largely due to the natural multiplication of a single species.

Period of Service of a Filter and its Influence upon Bacterial Efficiency.

The efficiency of a filter in removing bacteria increases as the organic matter upon and between the sand grains increases. The volume of water that can pass through the filter in a given time decreases as the organic matter increases. A new filter containing sand of an effective size of 0.23 millimeter, such sand as in filters Nos. 3 B and 8 A, will, with an acting head equal to the depth of the filter, allow water to pass at the rate of 43,000,000 gallons per acre daily; the desired rate of filtration being obtained by checking the flow at the outlet of the filter. As the surface clogs, this need of checking the flow grows less, until even with the outlet gate wide open and with an acting head equal to the depth of the filter the rate of flow will not be equal to the rate of filtration desired. The filter

surface is then scraped and the removal of sediment and organic matter puts the main body of sand in a condition such that its maximum rate is nearly or quite equal to its initial maximum rate. As the filter continues in operation, however, the organic matter gradually penetrates deeper into the body of sand, so that the maximum rate becomes decidedly less, even with a freshly scraped filter surface. This organic matter not only retards the flow of water but acts in the same manner as the surface scum or schmutüdecke in removing bacteria, and is of especial value in making good bacterial efficiency possible when the filter is first put into operation after a surface disturbance.

At the end of 1896, after filters Nos. 3B and 8A had been in operation for more than three years, an examination of the sand in each filter showed the following amounts of nitrogen present in parts per 100,000 by weight of dry sand:—

Nitrogen.
[Parts per 100,000.]

Beach Sand and Berkshire Sand.

Upon Sept. 2, 1895, a filter was constructed containing 48 inches in depth of sand obtained from Plum Island, twenty miles from Lawrence, upon the seashore. The object of this filter was to study the efficiency in water filtration of sand from a different locality, and perhaps of a differently shaped grain from the sands of the vicinity of Lawrence which had been used in all the water filters previously constructed at the station.

Two filters were also constructed at the same time of Berkshire sand, a white, sharp, pure quartz sand, such as is used in the manufacture of glass. These filters contained 24 and 12 inches in depth of sand respectively.

During the first year of operation of Filter No. 62, containing the beach sand, its bacterial efficiency was 98.93 per cent., and during its second year its efficiency was 99.25 per cent. Its rate of operation for the two years was 4,700,000 and 4,880,000 gallons per acre daily respectively. Comparing these results with those obtained by filters Nos. 48 and 49, in operation during 1893, 1894 and 1895, and containing Lawrence sand of about the same effective size as the beach sand, shows that the beach sand was fully as efficient as the Lawrence sand. The same statement can also be made in regard to the Berkshire sand.

The Water taken from the Merrimack River and applied to the Experimental Filters.

The water applied to the filters during 1896 has been Merrimack River water taken from the Essex Company's canal. The large 12-inch pipe from the canal to the station was removed during the year and a new 6-inch pipe laid. This new pipe is under ground, while the 12-inch pipe was above ground and could not be used during cold weather, making us dependent upon water drawn through a small pipe from the canal. With the new pipe an ample supply can be obtained at all seasons.

The results of the analyses of the water as it flows upon the filters are given in the next two tables; the first giving the average daily results of two or more bacterial determinations and the second giving the monthly averages of the chemical analyses, together with the results of bacterial determinations of samples taken at the same time that the samples for chemical analysis were taken.

Application of Bacillus Prodigiosus.

Pure cultures of B. prodigiosus were applied, together with the canal water, to filters Nos. 3B, 7A, 8A, 33, 43, 68, 69 and 79, at different periods from July to November. The method of applying the germs has been described in earlier reports (see annual report of the Board for 1892, page 529), and during 1896 the same system has been followed, except that they were applied in smaller numbers. The pure culture of B. prodigiosus was prepared for application by inoculating a solution containing one-tenth of a per cent. of peptone and two-tenths of a per cent. of glucose dissolved in city water with a pure culture of the bacilli and allowing them to grow four days at 20 degrees C. This mixture was applied to filters Nos. 3B, 7A and 8A, from July 1 to October 6, in the proportion of one part of the mixture to 170,000 parts of canal water, at intervals of one hour for ten hours a day on six days in a week.

From July 26 to November 30 the mixture was applied to filters Nos. 68 and 69, and from October 27 to November 30 the mixture

was applied to Filter No. 79, in the proportion of one part to 170,000 parts of canal water.

As has been stated on page 525, the effluent from Filter No. 33 A often contained great numbers of bacteria. In order to determine whether these organisms worked their way through the filter by channels in the sand, the *B. prodigiosus* mixture was applied to 33 A, in the proportion of one part to 170,000 parts of canal water, from July 14 to 28. On September 21 the amount was doubled and the mixture applied for two weeks in the proportion of one part to 85,000 parts of canal water. On October 26 and 30, November 6 and 16, the mixture was applied for one day in the same proportion.

Besides the filters already mentioned, Filter No. 43 was tested on November 16 by the application of one part of mixture to 85,000 parts of canal water.

The following table contains the average number of B. prodigiosus cells per cubic centimeter in the applied water:—

Average Number per Cubic Centimeter of Bacillus Prodigiosus in Applied River Water for Ten Hours Daily, 1896.

Work of the Water Filters, 1896.

The remainder of this report upon water filtration gives the details in regard to the construction and operation of the water filters, together with tables of the results obtained.

Filter No. 3 B.

This intermittent filter, one two-hundredth of an acre in area, was started Sept. 23, 1893, and contained 60 inches in depth of sand of an effective size of 0.23 millimeter. The history of this filter up to Jan. 1, 1896, has been published in the annual reports of the Board. The method of treatment and the points in connection with the operation of the filter which were of special importance during 1896 are described in the following paragraphs.

The whole number of gallons filtered during the year amounted to 4,630,261, and the rate averaged 2,867,000 gallons per acre daily. The gate in the canal water pipe was closed daily (excepting Sundays) at 5 A.M. The surface became and remained uncovered for two hours during the warmest part of the day as a result of this treatment. On October 31 a roof of heavy planking was built over the filter in order to protect it from the weather; on November 12 the top and sides of this roof were covered with two feet of sand. From June 13 to 19 Filter No. 3B ran continuously. During the years 1893, 1894, 1895 and part of 1896 the filter ran continuously on Sunday, excepting when closed, but after Nov. 1, 1896, the filter ran intermittently on Sunday, excepting when closed. The largest of the two pipes which supplied the filter with canal water was closed on account of cold weather in November, 1895. The rate of Filter No. 3 B was therefore reduced to 1,500,000 gallons per acre daily from Nov. 24, 1895, to April 19, 1896. On April 20 the rate was increased to 4,000,000 gallons per acre daily; and the rate was again increased on June 29 to 5,000,000 gallons per acre daily. On the days when the gate was opened after scraping, and on several days after the filter had stood closed for several hours on account of low water in the canal, the filter ran continuously for twenty-four hours. High water in the river flooded the filter on March 1, and the gate in the effluent pipe was shut until March 9. On March 10 the filter was drained, the river silt scraped from the surface and the filter filled slowly with city water from below.

Owing to the fact that the water was drawn down in the canal, the gate on the outlet had to be closed for periods varying from three to four hours on the following dates: January 4, 12, 26, February 6, 9, 16, May 2, 16, 23, 30, June 27, July 11, 25, August 1, 11, September 12, 19, 26, October 17, November 7, 14. The gate was also closed on the following dates for longer periods: during the freshet on March 1 the gate was closed for two hundred and fifty-four hours; for sixty-nine hours while the new canal pipe was being laid, on August 7, 8, 9; and for sixty-three hours on September 5, 6, 7. During all of these periods the filter remained covered with water.

In order to remove clogging at the surface, one-half an inch of sand (approximately) was removed by scraping the surface on January 3, 29, February 11, May 11, 27, June 17, July 7, 21, August 5, 13, 31, September 24, October 13, 22, 29, November 10, 19, December 10, 31. After scraping the surface, the filter was raked to a depth of 1 inch and city water was applied slowly from below until it covered the surface. After the surface became covered, canal water was applied and the filter put into operation, as soon as the depth of water on the surface reached 16 inches. On March 24 a strip 3 feet wide was scraped across the filter, the sand below this strip was then spaded 6 inches deep, and canal water applied at once from above. This experiment was tried in order to show the effect produced by scraping and disturbing a small section of a filter at a time. On April 8 and November 19 the whole surface was scraped, and then spaded over from 6 to 9 inches deep. Canal water was applied upon the surface instead of filling from below after scraping on April 8. A slight growth of spirogyra appeared on the surface of the filter during July and August. The exposure to the sun's rays while the surface was uncovered each day checked the growth of this algæ and prevented it from forming such great masses as developed upon continuous Filter No. 8A. The mixture of B. prodigiosus (described on page 533) was applied to Filter No. 3 B for ten hours a day from July 1 to November 24, in the proportion of one part to 33,000 parts of canal water.

Bacteriological analyses were made each day, excepting on Sundays, of four samples of effluent collected at different hours. The average number of bacteria per cubic centimeter found in these sets of samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in the Effluent of Filter No. 3 B, 1896.

Filter No. 7A.

This continuous filter, one two-hundredth of an acre in area, was started July 20, 1894, and contained 24 inches in depth of sand of an effective size of 0.26 millimeter. The history of the filter up to Jan. 1, 1896, has been published in the annual reports of the Board. The points in connection with the operation of the filter which were of special importance during 1896 are described in the following paragraphs.

The filter was not operated from Nov. 24, 1895, until April 13, 1896, but on the latter date was put in operation at a prescribed rate of 5,000,000 gallons per acre daily. The whole number of gallons filtered amounted to 4,813,825, and the rate averaged 4,124,000 gallons per acre daily for the period of operation. A short trap attached to the outlet prevented air from entering the filter at the bottom.

Spirogyra grew in masses and clogged the surface of the filter badly during July and August. The depth of water on the surface of the filter was kept at 32 inches until July 1, when it was reduced to 16 inches. A roof of heavy planking was built over the filter on October 31 in order to protect it from the weather, and the top and sides of the roof were covered with 2 feet of sand on November 12.

Owing to low water in the canal the gate on the outlet was closed for periods varying from three to twenty-four hours on the following dates: May 2, 16, 23, June 27, July 11, 25, August 1, 11, September 12, 19, 26, October 17, November 7, 14, 21. The gate was closed on the following dates for a longer period of time: from April 17 to 20 for sixty-one hours, on account of high water; from August 7 to 9 for sixty-nine hours; and September 5 to 7 for sixty-three hours. During all of these periods the surface remained covered with water.

In order to remove clogging at the surface, one-half an inch of sand (approximately) was removed by scraping the surface of the filter on May 9, 30, June 25, July 15, 22, August 7, 20, September 1, 15, October 2, 14, 23, November 12, 28.

After scraping, the filter was filled slowly with city water from below, and as soon as the surface became covered canal water was turned on, and the gate on the effluent pipe opened when the depth of water on the surface reached 16 inches. After scraping and filling from below on May 30, the gate on the effluent pipe was closed for fifty hours. Instead of being scraped the surface was raked 1 inch in order to remove clogging, and the filter filled slowly from below with city water on December 24.

A mixture containing a pure culture of B. prodigiosus was applied for ten hours a day from July 1 to October 9, in the proportion of one part of mixture to 170,000 parts of applied canal water.

Bacteriological analyses were made each day excepting Sunday of four samples of effluent collected at different hours, and the average number of bacteria per cubic centimeter found in these samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 7 A, 1896.

Filter No. 8 A.

This continuous filter, one two-hundredth of an acre in area, was started Sept. 26, 1893, and contained 60 inches in depth of sand of an effective size of 0.23 millimeter. The history of this filter up to Jan. 1, 1896, has been published in the annual reports of the Board. The points in connection with the operation of the filter which were of special importance during 1896 are described in the following paragraphs.

From Nov. 25, 1895, to April 19, 1896, Filter No. 8 A ran at a prescribed rate of 1,500,000 gallons per acre daily. The rate was increased to 5,000,000 gallons per acre daily on April 20, 1896. The whole number of gallons filtered during the year amounted to 5,984,000, and the rate averaged 3,694,000 gallons per acre daily for the days of operation. A trap attached to the outlet prevented air from entering at the bottom. On October 31 a roof of heavy planking was built over the filter in order to protect it from the weather, and the top and sides of this roof were covered with 2 feet of sand on November 12.

Spirogyra began to appear on the surface about July 1, and at times the water over the surface of the filter became completely filled with masses of these filaments. This growth of algae developed

so rapidly and clogged the sand to such a degree that the surface had to be scraped four times between July 6 and August 3.

Owing to the fact that the water was drawn down in the canal. the gate on the outlet was closed on the following dates, for periods varying from three to twenty-four hours: January 12, February 9, 16, May 2, 16, 23, 30, June 27, July 11, 25, August 1, 11, September 12, 19, 26, October 17, November 7, 14, 21. The gate was closed for longer periods on the following dates: March 1 to 11 for two hundred and thirty-eight hours on account of the freshet; April 17, 18, 19 for sixty-one hours on account of high water; August 7, 8, 9 for seventy-one hours while the new canal pipe was being laid. During all of these periods the surface of the filter remained covered with water. The freshet on March 1 covered the surface of the filter with silt. On March 10 the filter was allowed to drain, the river silt removed, and the filter filled slowly from below with city water. The gate was opened on March 11 and the filter started at a prescribed rate of 1,500,000 gallons per acre daily. On August 3 canal water was applied immediately at the surface after scraping.

In order to remove clogging at the surface one-half an inch (approximately) of sand was removed by scraping on the following dates: January 4, February 6, April 11, May 21, June 15, July 6, 20, 28, August 3, 15, September 11, October 12, November 9, December 1, and after scraping, the surface of the filter was raked to the depth of 1 inch. In order to remove clogging at the surface more efficiently, the surface was spaded from 6 to 8 inches deep after scraping on April 11, August 15, December 1. The filter was usually filled slowly from below with city water after scraping, and as soon as the surface became covered, canal water was turned on and the gate on the outlet opened. On August 15 and December 1 the gate was closed for twenty-four hours after filling with city water before the filter went into operation.

B. prodigiosus mixture was applied from July 1 to October 9 in the proportion of 1 part of mixture to 170,000 parts of applied canal water, and from October 10 to 24 the mixture was applied in the proportion of 1 part to 85,000 parts of applied canal water.

Bacteriological analyses were made each day excepting Sunday of four samples of effluent collected at different hours. The average number of bacteria found in each of these sets of samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in the Effluent of Filter No. 8 A, 1896.

Filter No. 18A.

This intermittent filter, 20 inches in diameter, was started Sept. 17, 1889, and contained 62 inches in depth of sand of an effective size of 0.48 millimeter. On Aug. 31, 1895, the depth of sand in the filter was reduced to 36 inches. Before the filter went into operation in 1896 the bed of sand in the filter was restored to its original depth. The history of the filter up to Jan. 1, 1896, has been published in the annual reports of the Board, and the points in connection with the operation of the filter which were of special importance during 1896 are described in the following paragraphs.

After draining, the filter went out of operation on Nov. 24, 1895. One foot of sand was taken out from the top of Filter No. 18 A on May 6, 1896, the sand remaining spaded to a depth of 1 foot, and enough sand added to restore the bed to its original depth of 62 inches. The sand used for this purpose was obtained by mixing the foot of sand taken out from 18 A with sand taken from Filter No. 50, which had been in operation during 1895 and contained sand of an effective size of 0.48 millimeter.

May 7 the filter was filled slowly from below with city water and allowed to stand over night, and on May 8 went into operation at a prescribed rate of 5,000,000 gallons per acre daily. The operation of the filter was arranged in such a manner that the surface remained uncovered for two hours during the day. The filter ran continuously on Sundays.

Owing to low water in the canal the gate on the outlet was closed on the following dates for periods varying from two to twenty-four hours: May 18, 23, June 27, July 13, August 9, 11, September 12, 19, 26, October 17, November 7. The gate was closed for a longer period of sixty-four hours on September 5, 6, 7. During all of these periods the surface remained covered with water.

In order to remove clogging at the surface the filter was scraped as follows: July 3, 0.26 of an inch of sand was removed; August 7, 0.23 of an inch; October 19, 0.49 of an inch; October 29, 0.41 of an inch; November 12, 0.44 of an inch. After scraping, canal water was applied from above without first raking the surface of the filter or filling from below with city water.

A bacteriological analysis of a sample of the effluent was made daily excepting Sundays. The number of bacteria per cubic centimeter found in these samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 18 A, 1896.

Filter No. 33 A.

This continuous filter, 20 inches in diameter, was started April 28, 1892, and contained 60 inches in depth of sand of an effective size of 0.14 millimeter. The history of the filter up to Jan. 1, 1896, has been published in the annual reports of the Board, and the points in connection with its operation during 1896 which were of special importance are described in the following paragraphs.

The filter went out of operation on Nov. 24, 1895, and on May 8, 1896, was again started at a rate of 2,000,000 gallons per acre daily. A short trap attached to the outlet prevented air from entering at the bottom of the filter.

For purposes of experiment Filter No. 33 was flooded with city (filtered) water instead of canal water on September 25 for twenty-four hours; on October 22, 23 and 24; and on November 23 for twenty-nine hours.

Owing to low water in the canal the gate on the outlet was closed on the following dates for periods varying from two to twenty-four hours: May 16, 23, 30, June 27, July 11, August 9, 11, September 12, 19, 26, October 17, 24, 28, November 4, 7, 14, 21. The gate was closed for a period of sixty-two hours on September 5. During all of these periods the surface remained covered with water. As explained on pages 525-529, the bacteria found in the effluent from Filter 33 A increased very greatly in number during the periods when the gate was closed. The great number of bacteria seems to have been due to the multiplication of cells belonging to a single species, which found the conditions existing in the filter at the time to be especially favorable for their development.

In order to remove clogging at the surface the filter was scraped on the following dates: July 30, 0.31 of an inch of sand was removed; October 5, 0.44 of an inch; and November 30, 0.29 of an inch. A mixture containing a pure culture of B. prodigiosus was applied in the proportion of 1 part of mixture to 170,000 parts of applied canal water, from July 14 to 31; in the proportion of 1 part to 85,000 parts of applied canal water, from September 21 to October 5; and in the same proportion on November 6 and 16.

A bacteriological analysis of a sample of the effluent was made daily, excepting Sundays, up to November 1. The number of bacteria per cubic centimeter found in these samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 33 A, 1896.

Filter No. 43.

This continuous filter, 20 inches in diameter, was started May 30, 1893, and contained 60 inches in depth of sand of an effective size of 0.26 millimeter. The history of the filter up to Jan. 1, 1896, has been published in the annual reports of the Board, and the points in connection with its operation during 1896 which are of special importance are described in the following paragraphs.

From Dec. 24, 1895, to July 28, 1896, the filter was not in operation. On the latter date it was started at the rate of 5,000,000 gallons per acre daily. Owing to low water in the canal the gate on the outlet was closed for periods varying from two to twenty-four hours on the following dates: August 9, 11, September 12, 19, 26, October 17, November 7, 14, 21. The gate was also closed for a longer period of sixty-two hours on September 5, 6 and 7. During all of these periods the surface remained covered with water. In order to remove clogging at the surface the filter was scraped on the following dates: September 12, 0.53 of an inch of sand was removed; October 5, 0.37 of an inch; November 26, 0.37 of an inch; December 22, 0.51 of an inch.

After scraping, canal water was usually applied at once without raking the surface or filling from below with city water. On November 26 the surface was spaded to a depth of 4 inches, city water applied slowly from below until the surface became covered, and the gate on the outlet closed for nineteen hours.

A mixture containing a pure culture of B. prodigiosus was applied,

in the proportion of one part of mixture to 85,000 parts of canal water, upon November 16, but the germ did not appear in the effluent.

A bacteriological analysis of a sample of the effluent was made on each day, excepting Sundays, from July 28 to November 13. The number of bacteria per cubic centimeter found in these samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 43, 1896.

Filter No. 62.

This continuous filter, 20 inches in diameter, was started Sept. 2, 1895, and contained 48 inches in depth of sand of an effective size of 0.40 millimeter. The sand for this filter was obtained from the beach at Plum Island, on the seacoast, 20 miles from Lawrence. The history of the filter up to Jan. 1, 1896, has been published in the annual report of the Board, and the points in connection with the operation of this filter during 1896 which are of special importance are described in the following paragraphs.

After draining, the filter went out of operation on Nov. 24, 1895. On May 11, 1896, city water was applied slowly from below until the surface became covered, canal water turned on, and the filter put into operation at a rate of 5,000,000 gallons per acre daily. When the filter was started, on May 11, it contained 39 inches of sand. A short trap attached to the outlet prevented air from entering the filter at the bottom. On account of low water in the canal the gate on the outlet was closed on the following dates for periods varying from two to forty-two hours: May 16, 23, 30, June 27, July 11, August 10, 11, September 12, 19, 26, October 17, November 7. The gate was closed for a longer period of sixty-two hours on September 5, 6, 7. During all of these periods the surface remained covered with water.

On May 25 the surface was found uncovered, therefore city water was applied slowly from below and canal water turned on as soon

as the surface became covered. In order to remove clogging, the surface was scraped on the following dates: July 6, 0.40 of an inch of sand was removed; July 27, 0.36 of an inch; August 11, 0.39 of an inch; August 25, 0.34 of an inch; September 11, 0.30 of an inch; October 2, 0.33 of an inch; October 28, 0.28 of an inch; November 10, 0.48 of an inch. After scraping, canal water was applied at once, without raking the surface or filling the filter from below with city water.

A bacteriological analysis of the effluent was made on each day excepting Sundays. The number of bacteria per cubic centimeter found in these samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 62, 1896.

Filter No. 63.

This continuous filter, 20 inches in diameter, was started Sept. 2, 1893, and contained 24 inches in depth of sand of an effective size of 0.16 millimeter. The sand used in this filter was a white, sharp, pure quartz sand, from Berkshire County, such as is used in the manufacture of glass. The history of the filter during 1895 was published in the annual report of the Board, and the points in connection with the operation of the filter during 1896 which are of special importance are described in the following paragraphs.

After draining, the filter went out of operation Nov. 24, 1895. The surface was spaded 4 inches deep on May 7, 1896, and enough new Berkshire sand added to make the bed of sand 24 inches deep; city water was then applied from below. After the surface became covered the filter was allowed to stand for sixteen hours. Canal water was applied May 8, and the filter put into operation at a rate of 5,000,000 gallons per acre daily. This rate was reduced to 3,000,000 gallons on June 1. A short trap attached to the outlet prevented air from entering at the bottom.

On account of low water in the canal the outlet of the filter was closed on the following dates for periods varying from two to twenty-four hours: May 16, 22, 23, 30, June 27, July 11, August 9, 11, September 12, 19, 26, October 17, November 7. The gate was

closed for a longer period of sixty-two hours on September 5, 6, 7. During all of these periods the surface remained covered with water:

In order to remove clogging the surface was scraped on the following dates: on May 15, 0.21 of an inch of sand was removed; on May 21, 0.29 of an inch; on May 26, 0.20 of an inch; on June 17, 0.25 of an inch; on June 23, 0.22 of an inch; on June 30, 0.25 of an inch; on July 6, 0.28 of an inch; on July 15, 0.29 of an inch; on July 22, 0.29 of an inch; on July 28, 0.27 of an inch; on August 3, 0.23 of an inch; on August 14, 0.31 of an inch; on August 22, 0.29 of an inch; on August 31, 0.32 of an inch; on September 10, 0.30 of an inch; on September 24, 0.24 of an inch; on October 5, 0.33 of an inch; on October 14, 0.33 of an inch; on October 26, 0.32 of an inch; on November 3, 0.24 of an inch. After scraping, canal water was applied at once, without raking the surface or filling the filter with city water from below.

A bacteriological analysis of the effluent was made on each day excepting Sundays. The number of bacteria per cubic centimeter found in these samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 63, 1896.

Filter No. 64.

This continuous filter, 20 inches in diameter, was started Sept. 2, 1895, and contained 12 inches in depth of sand of an effective size of 0.16 millimeter. The sand used in this filter was also a white, sharp, pure quartz sand, from Berkshire County. The history of the filter during 1895 was published in the annual report of the Board, and the points in connection with the operation of the filter during 1896 which are of special importance are described in the following paragraphs.

After draining, the filter went out of operation Nov. 24, 1895. The surface was spaded four inches deep on May 7, 1896, and enough new Berkshire sand added to make the bed of sand 12 inches deep. City water was applied on May 8 and the filter put into operation at a prescribed rate of 5,000,000 gallons per acre daily. The depth of water on the surface at this time was 6 inches. A short trap attached to the outlet prevented air from entering the filter at the bottom. June 1 the rate was reduced to 3,000,000 gallons per acre daily. In order to keep the filter running at the required rate, the surface had to be scraped about once in 5 days from July 8 to July 27.

On account of low water in the canal the gate on the outlet was closed on the following dates for periods varying from two to forty-two hours: May 16, 22, 23, 30, June 27, July 11, August 9, 11,

September 12, 19, 26, October 17, November 7. The gate was closed for a longer period of sixty-two hours on September 5, 6, 7. During all of these periods the surface remained covered with water.

In order to remove clogging the surface was scraped on the following dates: May 12, 0.26 of an inch of sand was removed; May 15, 0.22 of an inch; May 20, 0.18 of an inch; May 23, 0.23 of an inch; May 27, 0.20 of an inch; June 2, 0.24 of an inch; June 8, 0.23 of an inch; June 15, 0.26 of an inch; June 22, 0.14 of an inch; June 27, 0.19 of an inch; July 3, 0.20 of an inch; July 9, 0.27 of an inch; July 16, 0.24 of an inch; July 22, 0.25 of an inch; July 27, 0.23 of an inch; July 31, 0.23 of an inch; August 5, 0.20 of an inch; August 13, 0.27 of an inch; August 19, 0.27 of an inch; August 26, 0.30 of an inch; September 1, 0.21 of an inch; September 9, 0.25 of an inch; September 16, 0.30 of an inch; September 24, 0.24 of an inch; October 3, 0.24 of an inch; October 9, 0.23 of an inch; October 15, 0.24 of an inch; October 21, 0.22 of an inch; October 27, 0.23 of an inch; November 2, 0.23 of an inch. After scraping, the surface was not raked, and canal water was applied at once, without filling with city water from below.

A bacteriological analysis was made of a sample of effluent on each day excepting Sundays. The number of bacteria per cubic centimeter found in these samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No 64, 1896.

Water Applied to Filters Nos. 68 and 69.

The water applied to filters Nos. 68 and 69 was polluted in a much greater degree than the Merrimack River water applied to the other experimental filters, as described in the following paragraph.

From May 18 to August 20 a small stream of sewage and a stream of Merrimack River water were allowed to flow simultaneously into the top of a tank from the bottom of which the water applied to filters Nos. 68 and 69 was being drawn. After August 21, however, the mixed sewage and canal water was allowed to stand for several hours before being turned upon the filters. From June 17 to 24 no sewage was mixed with the canal water.

The character of the water applied to filters Nos. 68 and 69 is shown in the table of chemical analyses on page 559.

Bacteriological analyses have been made on each day, excepting Sundays, of at least three and sometimes four samples of the water collected at different hours. The average number of bacteria per cubic centimeter found in these samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Water applied to Filters Nos. 68 and 69, 1896.

Filter No. 68.

This continuous filter, 20 inches in diameter, was started on May 18, 1896, and contained 5 feet in depth of sand of an effective size of 0.23 millimeter. The points in connection with the construction and operation of this filter which are of special importance are described in the following paragraphs.

The underdrains in this filter are 6 inches deep, and are constructed as usual. Above these underdrains 5 feet of sand, obtained in the neighborhood of Lawrence, were put into the filter dry. A short trap attached to the outlet prevented air from entering the filter at the bottom. City water was applied slowly from below on May 18 and as soon as the water covered the surface the gate on the outlet was closed and the filter allowed to stand inoperative for eighteen hours. The filter was put into operation on May 19, at a prescribed rate of 5,000,000 gallons per acre daily, and the character of the water applied is shown in the table of chemical analyses. The rate of filtration was reduced on May 25 to 2,500,000, and on August 2 to 1,000,000, gallons per acre daily.

On account of low water in the canal the gate on the outlet was closed on the following dates for periods varying from two to forty-three hours: May 23, 30, June 27, July 11, 15, August 9, 11, September 12, 19, 26, October 17, November 7, 14, 21. The gate was closed for a longer period of sixty-two hours on September 5, 6, 7. During all of these periods the surface remained covered with water. In order to remove clogging the surface was scraped on the following dates: June 3, 0.49 of an inch of sand was removed; June 15, 0.45 of an inch; June 26, 0.30 of an inch; July 9, 0.38 of an inch; July 22, 0.36 of an inch; August 5, 0.29 of an inch; October 12, 0.36 of an inch; November 2, 0.45 of an inch; November 25, 0.39 of an inch; December 7, 0.32 of an inch; December 21, 0.34 of an inch. After scraping, the surface was not raked, and the applied water was turned on at once, without filling with city water from below.

B. prodigiosus mixture was applied to Filter No. 68, in the proportion of one part of mixture to 170,000 parts of applied water, during November and December.

Bacteriological analyses were made on each day excepting on Sunday of two samples of effluent; one of these samples was collected in the forenoon and the other in the afternoon. The average number of bacteria per cubic centimeter found in each set of two samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 68, 1896.

Filter No. 69.

This intermittent filter, 20 inches in diameter, was started on May 18, 1896, and contained 5 feet in depth of sand of an effective size of 0.23 millimeter. The points in connection with the operation of this filter which were of special importance are described in the following paragraphs.

The filter was a duplicate of Filter No. 68. The sand was put into the filter dry, city water was applied slowly from below on May 18 until the surface of the sand became covered, and the gate on the outlet was then closed for sixteen hours. On May 19 Filter No. 69 went into operation as an intermittent filter, at a prescribed rate of 5,000,000 gallons per acre daily. The period of intermittent operation was arranged in such a manner that the surface became and remained uncovered for two hours during the day. The rate of filtration was reduced on May 25 to 2,500,000 gallons per acre daily, and on August 20 to 1,000,000 gallons. A short trap attached to the outlet prevented air from entering the filter at the bottom.

Owing to low water in the canal the gate on the outlet was closed on the following dates for periods varying from two to forty-two hours: May 23, 30, June 27, July 11, August 9, 10, 11, September 12, 19, 26, October 17, November 7, 14, 21. The gate was closed for a longer period of sixty-three hours on September 5, 6, 7. During all of these periods the surface remained covered with water.

In order to remove clogging the surface was scraped on the following dates: May 27, 0.29 of an inch of sand was removed; June 4, 0.48 of an inch; June 8, 0.26 of an inch; June 11, 0.30 of an

inch; June 15, 0.29 of an inch; June 18, 0.29 of an inch; June 26, 0.25 of an inch; July 2, 0.26 of an inch; July 9, 0.31 of an inch; July 21, 0.28 of an inch; July 28, 0.24 of an inch; August 15, 0.31 of an inch; August 31, 0.27 of an inch; September 4, 0.22 of an inch; October 15, 0 35 of an inch; October 27, 0.44 of an inch; November 18, 0.30 of an inch; November 27, 0.34 of an inch; December 5, 0.39 of an inch; December 11, 0.25 of an inch; December 17, 0.32 of an inch; December 28, 0.23 of an inch. On September 4 the surface was spaded to a depth of 2 inches after scraping; but on other occasions the applied water was turned on at once, without raking the surface or filling from below with city water.

B. prodigiosus mixture was applied to this filter, during November and December, in the proportion of one part of mixture to 170,000 parts of applied water.

Bacteriological analyses were made on each day excepting on Sunday of two samples of effluent; one of these samples was collected in the forenoon and the other in the afternoon. The average number of bacteria per cubic centimeter found in each set of two samples is given in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 69, 1896.

Water Applied to Filter No. 79.

The effluent from filters Nos. 68 and 69 was applied to Filter No. 79, and a bacteriological analysis was made on each day, excepting Sundays, of a sample of the water. The number of bacteria per cubic centimeter found in these samples is given in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in the Water Applied to Filter No. 79, 1896.

Filter No. 79.

This continuous filter was started on Sept. 18, 1896, and contained 5 feet in depth of sand of an effective size of 0.23 millimeter. The sand was put into the filter dry and city water applied below until the surface of the sand became covered with water. The gate on the outlet was then closed and the filter allowed to stand for twenty-four hours. On September 18 the filter went into operation at a prescribed rate of 3,300,000 gallons per acre daily. The water applied to this filter was a mixture of the effluents from filters Nos. 68 and 69. On November 23 18 inches of sand were removed from the top of Filter No. 79, and two sets of cleats were nailed to the inner sides of the walls. One set of cleats was fastened to the walls 18 inches below the level of the original surface of the sand, and the other set 12 inches below. The cleats were made with bevelled edges, which sloped towards the walls and projected one-quarter of an inch from the wood to which they were fastened, and by this arrangement formed pockets into which the sand settled and made a close joint between the walls of the filter and the bed of sand. As soon as the cleats had been put into position the sand which had been taken out was replaced. On November 24 city water was applied from below until the surface became covered with water. The gate on the outlet was then closed and the filter allowed to stand for twenty-four hours. When the filter went into operation again, on November 25, canal water instead of the effluents from filters Nos. 68 and 69 was applied. After filtering canal water for two weeks, the effluents from filters Nos. 68 and 69 were turned on again on December 7. The rate of filtration was increased to 4,700,000 gallons per acre daily on December 14.

Owing to low water in the canal the gate on the outlet was closed for periods varying from thirty-nine to forty-three hours on the following dates: September 19, 26, October 17, November 7, 14. During all of these periods the surface remained covered with water. In order to remove clogging the surface was scraped on the following dates: December 21, 0.37 of an inch of sand was removed; December 27, 0.36 of an inch was removed. After scraping, the applied water was turned on at once.

B. prodigiosus mixture was applied to this filter from October 25 to November 30, in the proportion of one part to 170,000 parts of applied water.

A bacteriological analysis was made on each day excepting on Sunday of a sample of the effluent from Filter No. 79. The average number of bacteria per cubic centimeter found in each of these analyses is given in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 79, 1896.

LAWRENCE CITY FILTER.

The filter of the water supply system of the city of Lawrence is 2.5 acres in area, was first put into operation Sept. 20, 1893, and its construction and action were described in the report of the State Board of Health for that year. From the date of starting this filter up to the present time it has been in continuous use, and not once has the unfiltered river water entered the reservoir or the service pipes of the city water supply. The filter is still uncovered, and hence unprotected from the severe cold of the winters of the climate of Lawrence. As a result of this, a thick coating of ice forms upon the filter and has to be removed to enable the surface to be scraped. The surface is very much disturbed by the removal of the ice, and the bacterial efficiency of the filter is not, at times, as good as it otherwise would be.

The effect of this filter upon the health of the people of Lawrence is well shown by the following table, giving the deaths from typhoid fever in the city during the period 1885 to 1896 inclusive. Many of the deaths are of operatives in the mills which are piped with the unfiltered river water.

Deaths from Typhoid Fever in Lawrence, 1885-96.

| 1896, | | | | | | | | 10 | 1.86 | 2 | 4 |

The daily bacterial determinations made during the winter of 1895-96 were given in the last report. During the summer of 1896 bacterial determinations were made once each week, and from Dec. 1, 1896, to April 30, 1897, daily, except Sundays and on a few other occasions. All the determinations made are given in the tables.

The bacteria found in the filtered water at the different points occasionally numbered more than 100 per cubic centimeter. These high numbers were partly due to the following causes:—

From May 14 to June 1 a species of bacillus which was common in the air appeared in the water at the outlet of the reservoir in considerable numbers. The bacillus was found in the tap water at the city hall after May 20, and in the tap water at the experiment station after May 24. During the last week in May the filter was scraped, spaded 10 inches deep and restored to its original level with washed sand. During the week which preceded July 20 repairs were made in the force main leading from the pumping station to the reservoir. During this period the sediment which had collected within the main at certain places was scraped off and passed into the reservoir. From August 10 to 22 engineers made a series of tests on the pumps at the station and on the water main. The force main leading from the pumps to the reservoir was tapped at several places and gauges were attached. The water was drawn out of the main and its interior partially scraped, and finally a weir was constructed about the overflow of the force main in the reservoir, to measure the volume of water pumped. About September 1 the floor in the station at one side of the pump well was torn up, in order to build the foundation for a new pump, and a pipe was laid from the pump into the well. While these changes were being made, foreign matter of various kinds was washed into the filtered water in the pump well and pumped up into the reservoir. This work of construction lasted until November 30.

The high number of bacteria in the tap water at the experiment station on October 30 was due to dirt which washed into the pipe during repairs in the water main.

Number of Bacteria per Cubic Centimeter in the Lawrence City Water before and after Filtration.

The following tables give the averages of the chemical analyses of the river water and also of the filtered water collected at various points on the water supply system once each week during the year. The bacterial results given in these tables are of these samples only.

Monthly Averages of Analyses of the Merrimack River Water as it flows upon the Lawrence City Filter.

SEWAGE DISPOSAL

OF

CITIES AND TOWNS IN MASSACHUSETTS

вт

INTERMITTENT FILTRATION.

[579]

SEWAGE DISPOSAL OF CITIES AND TOWNS IN MASSACHU-SETTS BY INTERMITTENT FILTRATION.

During the year 1896 works for the disposal of sewage were constructed at Natick, Leicester and the Westborough Insane Hospital. The results of examinations of sewage and effluent collected from the various works and examined during the year 1896 are given in the tables which follow, together with statistics as to the works. At the end of 1896 there were 11 cities and towns in the State in which the purification of the sewage is effected by filtration through beds of gravel or sand, and the sewage of several large institutions is disposed of by this method.

SEWAGE DISPOSAL AT BROCKTON.

The sewage disposal works of the city of Brockton were first put in operation in November, 1894. The total number of connections delivering sewage to the sewers during the last quarter of 1896 was 309, of which 154 were from dwelling-houses and 155 from factories, business blocks, hotels and public buildings.

The following table, taken from the report of the city engineer of Brockton for 1896, gives the average amount of sewage disposed of and the average temperature of the sewage as it reached the beds:—

| | | | Мо | NTH. | | | | Average Daily Flow at Field (Gallons). | Temperature Sewage at Field (Degrees F.). |
|-----------|---|--|----|------|--|--|--|--|--|
| January, | _ | | | | | | | 474,000 | 43.5 |

| une | | | | | | | | 381,700 | 56.3 |
| nly, . | | | | | | | | 322,800 | 59.9 |
| Lugust, | | | | | | | | 365,900 | 62.2 |
| eptember. | | | | | | | | 527,100 | 61.0 |
| ctober. | | | | | | | | 600,100 | 57.4 |
| Tovember, | | | | | | | | 616,000 | 54.1 |
| December. | | | | | | | | 559,000 | 49.9 |

The results of examinations of the sewage and effluent from these works made in March, 1897, are given below.

Odor, offensive. — The samples were collected as the sewage flowed out upon the filter beds. The first sample was collected when the sewage contained a large amount of sludge, occasioned by the agitation of the sewage in the receiving reservoir.

Odor, musty. — The sample was collected from the underdrain near Pearl Street, and contains a large amount of ground water.

SEWAGE DISPOSAL AT FRAMINGHAM.

At the end of 1896 about 850 dwelling-houses and 50 business blocks, stores, factories, etc., were connected with the sewers. The Women's Prison, having a population of about 300, located within the limits of the town of Sherborn, is also connected with the works.

Analyses of samples of the sewage and effluent collected during the year are given in the tables which follow:—

Odor of the first and last samples, vegetable; of the second, none, becoming faintly mouldy on heating. — The samples were collected from the brook, at the first road crossing below the sewage field.

SEWAGE DISPOSAL AT GARDNER.

The area used for the disposal of sewage at Gardner was enlarged in 1896 by the construction of several new filter beds, bringing the total area up to about 2.75 acres. The quantity of sewage delivered to the filter beds is not definitely known. At the end of 1896 the sewers were used by 432 families, 38 business blocks, hotels and public buildings, 5 school-houses and 11 factories, and it is estimated that the total number of people connected with the sewers is about 5,500. The total length of the sewers is a little over 9 miles.

Odor, decidedly musty and disagreeable. - The samples were collected from the brook below the filter beds and below the point where effluent from the filter beds enters the stream.

SEWAGE DISPOSAL AT LEICESTER.

Works for disposing of the sewage of the central village of the town of Leicester were constructed in 1896 but were only partially completed at the end of the year. They will be described in a subsequent report.

SEWAGE DISPOSAL AT MARLBOROUGH.

Additions have been made during 1896 to the works for purifying the sewage of Marlborough, and the total area of filter beds and sludge beds in use at the end of the year, including the beds constructed during the year, was 14.6 acres.

Chemical Examination of Sewage from Marlborough.

The samples were collected from the spring which is located north of the filter beds and a little over 260 feet from the edge of the nearest bed. The ground where the filter beds are located slopes in the direction of this spring.

No. 34.7

SEWAGE DISPOSAL AT NATICK.

Population in 1895, 8,814. A system of sewerage and of sewage disposal was put in operation in the latter part of 1896 for collecting and disposing of the sewage of the town of Natick.

The sewage is collected on the westerly side of the thickly settled portion of the town and conveyed to a pumping station near the south-westerly end of Lake Cochituate, from which it is pumped to a sewage-disposal area located near the Worcester turnpike and on the opposite side from the area used by the town of Framingham. The filtration area contains nearly 100 acres, three-quarters of which can apparently be utilized for filtration purposes. About three acres of filter beds were prepared for use in the beginning with underdrains discharging into Bannister Brook, just above the Framingham filtration area.

A further description of these works, together with analyses of the sewage and effluent, will be given in a subsequent report.

[599]

FOOD AND DRUG INSPECTION.

The operations of the Board under the provisions of the food and drug acts for the year ending Sept. 30, 1896, are detailed in the following report.

The following persons comprised the force employed by the Board during the year: —

| Dr. Charles P. Worces | TER, | , . | | | Analyst. |
|-------------------------|------|-----|--|--|--------------------|
| Prof. Charles A. Goessi | | | | | |
| Mr. Albert E. Leach, | | | | | Assistant Analyst. |
| JOHN H. TERRY, . | | | | | Inspector. |
| JOHN F. McCAFFREY, | | | | | Inspector. |
| Horace F. Davis, . | | | | | |
| THOMAS O. ALLEN, . | | | | | Inspector. |

The whole number of samples of food and drugs (including milk) examined during the year was 8,357, or 1,048 more than the number examined in the year ending Sept. 30, 1895, and 2,453 more than the average annual number examined in the ten years from Sept. 30, 1885, to Sept. 30, 1895.

The whole number examined since the beginning of operations in this department in 1883 was 76,113.

The following summary embraces the work done during the year: —

| Number of samples of milk examined, | | 4,484 |
|--|--|-------|
| Number of samples above standard, | | 2,904 |
| Number of samples below standard, | | 1,580 |
| Percentage of adulteration or deficiency, | | 35.2 |
| Number of samples of other kinds of food (not milk), . | | 3,368 |
| Number of samples above standard, | | 2,978 |
| Number of samples below standard, | | 390 |
| Percentage of adulteration, | | 11.6 |
| Number of samples of drugs examined, | | 505 |
| Number of samples of good quality, | | 251 |
| Number of samples adulterated, as defined by the statutes, | | 254 |
| Percentage of adulteration, | | 50.3 |
| Total number of samples of food and drugs examined, | | 8,357 |
| Total number found to be of good quality, | | 6,133 |
| Total number not conforming to the statutes, | | 2,224 |
| Percentage of adulteration, | | 26.6 |

Attention has already been called, in previous reports, to the fact that the percentages given in the foregoing summary do not represent, in any degree, the actual ratio of adulteration existing in food products and in drugs, for several reasons: chiefly on account of the fact that the experience of the Board enables it, first, to exercise a careful selection of such articles, mainly, as are liable to adulteration; secondly, to obtain such articles in those seasons of the year when their adulteration is most common; and third, to pay special attention to new forms of adulteration which are constantly appearing as fast as the fraud and ingenuity of the professional adulterator present them to the public.

Legislation also has a marked effect upon the figures which represent the conditions of the food supply as found upon analysis. For example, a standard of milk was established by a statute of 1880, requiring that milk should be deemed to be not of good standard quality if not possessing 13 per cent. of total solids; but this law was amended in 1886 by a provision that the standard of quality during two months of the year (May and June) might be 12 per cent. of solids. In 1896 the law was further amended by providing that the number of months in which the standard should be 12 per cent. should be increased to five (April, May, June, July and August). Now, since the number of samples of milk ranging from 12 to 13 per cent. of solids invariably constitutes a large percentage of the whole number collected, the percentage of samples found to be below the legal standard would necessarily be materially diminished by such legislation, while the actual quality, as determined by analysis, might not be changed. This statement is corroborated by that of the principal analyst, to be found on a later page. years 1893, 1894 and 1895 the usual collections of milk submitted to examination showed a ratio of about 49 per cent. below the legal standard, while those of the past year, under the amended statute, gave only 35.2 per cent. below the standard.

The following tables present a summary of the work done during the entire period from the beginning of operations under the food and drug acts in 1883 to the close of the year ending Sept. 30, 1896:—

| Percentage of adulteration, | 31.5 | 32.8 | 33.7 | 31.2 | 31.9 | 38.5 | 26.6 | 34.2 |
| Expense of collection, examination and prosecution, | \$10,013 04 | \$10,019 41 | \$11,180 30 | \$10,454 11 | \$10,364 64 | \$11,375 89 | \$10,921 61 | \$127,448 24 |
| Expense of collection, examination and prosecution, per sample, | 1 07 | 1 00 | 1 00 | 20 1 | | 00 1 | | |

From the foregoing tables it appears that 76,113 samples of food and drugs have been collected by the inspectors of the Board and submitted to the analysts for examination during the fourteen years in which the statutes providing for this work have been in operation. The total cost of the work has been \$127,448.24. Enough has already been said in previous reports to show that many times this sum have undoubtedly been saved to the consumers throughout the State.

The cost of collection and analysis per sample has also been reduced nearly one-half. This expense in 1883 amounted to \$2.26 per sample, but this amount has been reduced to \$1.23 in 1896, a sum much less than that of any preceding year. Part of this saving is due to the concentration of the greater part of the work of analysis under one head at the State House laboratory.

By a requirement of the statute the greater part of the appropriation for the work of this department is expended in the inspection of milk and milk products and the enforcement of the laws relating to these valuable articles of food. Hence the greater portion of the samples collected are of this character.

In the last annual report the results of a single street collection of milk taken from milk wagons in one city were published, the average solids of 20 samples being 12.98.

Attention is called to the statement of the analyst relative to the change of standard and its effect upon the ratio of apparent adulteration, and the method of detection of formalin. A further table of analyses of condensed milk is also presented, in addition to those which were published last year. Analyses of eight samples of evaporated cream, of six different brands, are also presented, in which it is shown, as well as in the case of some of the brands of condensed milk, that the cream has been largely removed, thus depriving them of an important ingredient of high value as a nutrient.

The following table presents the results of analysis of the milk of 20 animals, all of which were of one herd of Holstein cows, which had the reputation of being an unusually good herd of cattle:—

| | | Time | | | | RESUL | rs of An | ALYSIS. | | |

For further analyses of milk of known purity see page 628.

The principal articles of food found to be adulterated during the year were olive oil, lard, honey, molasses, maple syrup and sugar, spices, especially cayenne, vinegar, coffee, cocoa and cream of tartar.

DRUGS.

The principal drugs found adulterated or below the standard were ether, alcohol, ammonia water and chlorine water, distilled water (in this article the solids varied from 0 to 73 per 100,000 parts), calx chlorata, extracts of liquorice and nux vomica, powdered opium, compound spirits of ether, spirits of nitrous ether, whiskey, tincture of iodine, syrup, tincture of opium, mercurial ointment, white and red wine.

NOTICES.

The following lists present the names of the cities and towns to which notices were issued relating to the adulteration of different kinds of food and drugs:—

PROSECUTIONS.

In the reports of the last four years a condensed summary was presented, showing the number of prosecutions conducted in each year since the beginning of work under the food and drugs acts. The following table presents the same figures, with the addition of those for the year ending Sept. 30, 1896:—

| Number of Complaints en | ntered i | n Court. |
|-------------------------|----------|----------|

^{*} To May 1, 1886.

Ratio of convictions to complaints, 91.4 per cent.

NOTE. — All complaints entered before May 1, 1886, were under the direction of the Board of Health, Lunaey and Charity, and all after that date were under the direction of the State Board of Health.

The following report was presented to the Legislature in January, 1897, in compliance with the provisions of the statutes:—

Office of the State Board of Health, State House, Boston, Jan. 1, 1897.

To the Honorable Senate and House of Representatives of the Commonwealth of Massachusetts in General Court assembled.

The following summary is made in compliance with the provisions of chapter 289, section 2, of the Acts of 1884, requiring the State Board of Health to "report annually to the Legislature the number of prosecutions made under chapter 263 of the Acts of 1882, and an itemized account of all money expended in carrying out the provisions thereof."

The whole number of prosecutions made by authority of the Board against offenders, under the provisions of the food and drug acts, for the year ending Sept. 30, 1896, was 75.

[†] Four months only.

[‡] No record kept.

STATE BOARD OF HEALTH.

The cities and towns in which the articles were sold, and in respect to which complaints were entered in court, the character of the articles found to be adulterated, or fraudulently sold, the dates of the trials, and their results, are presented in the following table: -

SUMMARY.

The whole number of complaints entered by the State Board of Health during the year ending Sept. 30, 1896, in the courts of the Commonwealth, against parties for violation of the statutes relating to food and drug inspection, was 75.

In 74, or 98.7 per cent., of these the parties were convicted. One was discharged in the municipal court.

Of the whole number, 68 were for violation of the laws relating to milk adulteration, and of this number 67 resulted in conviction. The greater number of these was for violation of the statute providing that milk offered for sale shall be of good standard quality.

In 10 of the foregoing cases the complaints were for sales of milk containing coloring matter.

The attention of the Legislature is again respectfully called to the provisions of chapter 425 of the Acts of 1894, which debars any private citizen from maintaining an action against a producer for selling adulterated milk.

Attention is also respectfully called to the provisions of section 23 of chapter 397 of the Acts of 1896, by which the people are now deprived of any legal protection against the harmful action of poisonous patent medicines.

All of the 7 parties against whom complaints were entered for fraudulent sales of other kinds of food were convicted.

The articles of food with reference to which these complaints were made were as follows:—

Maple sugar, 4 cases; maple syrup, 1 case; molasses, 1 case; cream of tartar, 1 case.

The following statute, as amended in 1896 (chapter 398), presents the standard of milk in Massachusetts at the date of publishing this report:—

[CHAPTER 398, SECTION 2, ACTS OF 1896.]

In all prosecutions under this chapter, if the milk is shown upon analysis to contain less than thirteen per cent. of milk solids, or to contain less

than nine and three-tenths per cent. of milk solids, exclusive of fat, or to contain less than three and seven-tenths per cent. of fat, it shall be deemed, for the purposes of this act, to be not of good standard quality, except during the months of April, May, June, July and August, when milk containing less than twelve per cent. of milk solids, or less than nine per cent. of milk solids exclusive of fat, or less than three per cent. of fat, shall be deemed to be not of good standard quality.

The following list presents the total solids in each of the samples of milk upon which complaints were founded, so far as records of the same were kept:—

| 7.09 | 10.00 | 10.52 | 11.04 | 11.30 |
|------|-------|-------|-------|-------|
| 7.13 | 10.20 | 10.56 | 11.06 | 11.30 |
| 8.69 | 10.20 | 10.57 | 11.10 | 11.39 |
| 8.75 | 10.24 | 10.62 | 11.11 | 11.42 |
| 9.20 | 10.24 | 10.64 | 11.14 | 11.44 |
| 9.26 | 10.34 | 10.66 | 11.16 | 11.60 |
| 9.32 | 10.38 | 10.77 | 11.18 | 11.64 |
| 9.71 | 10.40 | 10.79 | 11.19 | 11.76 |
| 9.80 | 10.42 | 10.86 | 11.25 | 11.78 |
| 9.81 | 10.42 | 10.90 | 11.26 | 12.60 |
| 9.84 | 10.43 | 10.96 | 11.28 | 12.62 |
| 9.92 | 10.49 | | | |

The total number of samples of food and drugs examined during the year was as follows: —

| | Milk, | | | | | • | | | | | | | | 4,484 |
|----|----------|---------|-------|--------|-------|----------|-------|-----|------|--------|----|--|---------|-------|
| | Other | article | s of | food, | | | | | | | | | | 3,368 |
| | Drugs. | , . | | | | | | | | | | | | 486 |
| | To | otal, | | | | | | | | | | | | 8,338 |
| To | tal expe | nses o | f col | lectio | n, e | xamina | ation | and | pros | ecutio | n, | | \$10,95 | 21 61 |
| Av | erage er | xpense | per | samp | ole o | collecte | ed, | | | | | | | 1 31 |

FINES.

The amount of fines paid into the treasuries of counties, cities and towns under the provisions of the general and special laws relative to the inspection of food and drugs was as follows:—

Fines paid for Violation of the Food and Drug Acts, upon Cases entered for the Year ending Sept. 30, 1896.

| Under the provisions | s of the | laws r | elating t | to milk a | ind milk | product | s, \$2,742 | 20 |

PROPRIETARY MEDICINES.

During the course of its work in the inspection of food and drugs, a considerable number of specimens of proprietary medicines has been examined by the analysts of the Board, and the results of analysis have been published in the annual reports. These published statements are scattered through different reports covering several years, and some of them are out of print. There is an increasing demand for the information contained in them, and it has been thought advisable to republish the results in a condensed form, in answer to this demand, with such additions as have been made during the past year.

The following list contains a condensed statement of the results of analysis of most of the proprietary articles alluded to above. In very many instances the preparations were examined for the presence of some single ingredient only, where this ingredient was found to be a poisonous substance, injurious to the health of persons using it.

Cosmetics.

The following contain acetate of lead (sugar of lead) or some active lead compound:—

| active lead compound: — | | Per Ce Lea | ad |
|---|------|---------------|------|
| | | Contai | |
| Ayer's Hair Vigor, contained the equivalent of about | | . (| 0.30 |
| "Renown" Hair Restorer, contained the equivalent of about . | | . 1 | 1.86 |
| Mrs. Allen's Hair Restorer, contained the equivalent of about. | | . 2 | 2.30 |
| American Hair Restorative, contained the equivalent of about. | | . (| 0.61 |
| Barrett's Vegetable Hair Restorative, contained the equivalent of a | bout | . 0 | .22 |
| Chevalier's Life for the Hair, contained | | . M | uch. |
| Hall's Vegetable Sicilian Hair Renewer, contained the equivalent of | abou | it 1 | 1.75 |
| Wood's Hair Restorative, contained the equivalent of about . | | . 1 | 1.59 |
| Ring's Vegetable Ambrosia, contained the equivalent of about | | . 1 | 1.51 |
| Parker's Hair Balsam, contained the equivalent of about | | . 2 | 2.32 |
| Wolf's Vegetable Hair Restorer, contained the equivalent of about | | . (| 0.95 |

Instances of lead poisoning have been known to occur from the free external use of such preparations as the foregoing.

The following contained corrosive sublimate, or some other poisonous salt of mercury, in the proportion of 1 to 15 grains per ounce:—

Harriet Hubbard Ayer's Recamier Cream, Balm and Lotion.

Madame Ruppert's World Renowned Face Bleach.

Madame Yale's Excelsior Complexion Bleach.

Hill's Freckle Lotion.

Soule's Freckle and Moth Eradicator.

Perry's Freckle Lotion.

Oriental Cream.

Mrs. McCorrison's Famous Diamond Face Lotion (14.7 grains to the ounce). Royal Cream.

In one instance a six-ounce bottle contained 47 grains of corrosive sublimate. Another contained 14 grains of the bichloride per ounce. It is not surprising that instances of serious harm were reported from the use of such articles.

Tonics and Bitters.

The following were examined for the purpose of ascertaining the percentage of alcohol in each. Some of them have been recommended as temperance drinks:—

| ended as temperance | | | | | (1 | Per Cent. of Alcohol by Volume).* |
|-------------------------|--------|--|--|--|----|---|
| "Best" Tonic, | | | | | | 7.6 |
| Carter's Physical Extra | | | | | | 22.0 |
| Hooker's Wigwam Ton | ic, . | | | | | 20.7 |
| Hoofland's German Tor | nie, . | | | | | 29.3 |

^{*} In this list the percentages of alcohol are reckoned by volume; in more recent lists, by weight. Percentages by volume may be converted into percentages by weight and vice versa by means of the table published in the U.S. Pharmacopaia of 1890, pages 531-537.

| Hop Tonic, | | | | | Per Cent. of Alcohol (by Volume).* |

| Radway's Resolvent, | | | | | | • | | | | 7.9 |

The dose recommended upon the labels of the foregoing preparations varied from a teaspoonful to a wineglassful, and the frequency also varied from one to four times a day, "increased as needed."

" Opium Cures."

Each of the so-called cures furnished by the following persons, mostly in Ohio, Indiana and Illinois, were found to contain morphine in variable amounts:—

| H. L. Baker. | J. C. Hoffman. |
|-------------------|------------------|
| J. C. Beck. | H. H. Kane. |
| C. C. Beers. | F. E. Marsh. |
| G. A. Bradford. | L. Meeker. |
| P. B. Bowzer. | Wm. P. Phelon. |
| J. S. Carleton. | Salvo Remedy Co. |
| S. B. Collins. | W. B. Squire. |
| B. S. Dispensary. | J. L. Stevens. |
| J. A. Drollinger. | B. M. Woolley. |
| J. R. A. Dunn. | · |

Dr. Buckland's Scotch Oats Essence.

The so-called Keeley's Double Chloride of Gold Cure, at first advertised as a remedy for the opium habit, was also examined by the Board in 1884, and found to contain not a trace of gold.

"Blood Purifiers."

An examination of the so-called "sarsaparilla" remedies, or "blood purifiers," was made in 1892, and in nearly every instance the remedy was found to contain iodide of potassium in variable amounts.

The following general comments upon these preparations were made in the report of that year:—

With but few exceptions they contain a considerable percentage of a very active and powerful remedy, the iodide of potassium. . . The sale of such an article in unlimited quantities by druggists, grocers and others is censurable. More than this, the method of its sale is dishonest, since the unwary purchaser is led to believe that he is purchasing a harmless vegetable remedy, namely, sarsaparilla.

It may be seriously questioned whether the blood of persons who take iodide of potassium continuously is not decidedly impoverished, instead of being purified, as is claimed by the manufacturers. It is not uncommon to find persons who have used continuously six, eight or ten pint bottles of one of these preparations.

Unlike sarsaparilla, the iodide of potassium is classed among poisons by nearly every writer upon toxicology.

The Board quotes several noted authorities upon this subject. The pale, sallow complexion of the habitual user of the "sarsaparilla iodides" is unfortunately too often met with, wherever these remedies are freely advertised and sold.

The following list presents the percentage of iodide of potassium found in those samples which have been submitted to the analyst for examination:—

| ·· So-callea | Sarsaparina | Kemeaies. |
|--------------|-------------|-----------|
| | | |
| | | |

| | Name | | Per Cent. of Iodide of Potassium. | Name. | Per Cent. of Iodide of Potassium. |
|--------------|------|--|---|---------------------|---|
| Wilson's, | | | 0.32 | Coleman & Co.'s, | 0.83 |
| Howe's, . | | | 0.33 | Bass's, | 0.84 |
| White's, . | | | 0.38 | Brown's, | 1.00 |
| No name, | | | 0.41 | Leavitt's, | 1.00 |
| Charles's, | | | 0.41 | Moriarty's, | 1.11 |
| Mahern's, | | | 0.41 | Dana's, | 1.17 |
| Ayer's, . | | | 0.45 | Woodward's, | 1.33 |
| Bartlett's, | | | 0.50 | Dudley's, | 1.50 |
| No name, | | | 0.50 | Cherry & Wingate's, | 1.55 |
| No name, | | | 0.50 | Jaynes's, | 1.59 |
| Packard's, | | | 0.58 | Nims's, | 1.67 |
| Raynsford's, | | | 0.58 | Cherry & Wingate's, | 1.67 |
| Adams's, | | | 0.75 | Mattison's, | 2.00 |
| Broad & Co. | s, | | 0.75 | Myrick's, | 2.12 |
| Hood's, . | | | 0.75 | Leavitt's, | 2.17 |
| Hutchinson's | 3, . | | 0.75 | Church's, | 2.25 |
| Dr. White's, | | | 0.75 | | |

The active ingredient was in nearly all instances the iodide of potassium, but in one or more of the samples the analyst states that the iodide "was in the form of iodide of iron, and in others probably the sodium salt."

In 1895 the attention of the Board was called to some cases of lead poisoning which had followed the use of certain carbonated syrups and other drinks of an effervescing nature. An examination was made, which resulted in finding that the stoppers of the bottles used for holding these drinks were often made in part of lead, the amount varying in 50 different samples from as low as 1 per cent. to a little over 50 per cent. of lead; and the contents of the bottles also contained variable amounts of lead, the maximum being in the proportion of 0.27 grain per gallon. This quantity would probably vary with the length of time during which the contents were exposed to the lead stoppers.

The following preparations were found to contain cocaine: -

Dr. Birney's Catarrhal Powder was found on analysis to contain hydrochlorate of cocaine, and according to the label each bottle contains 2½ per cent. of this drug, with other ingredients.

Instant Cold Relief, made by the Instant Cold Relief Company of Taunton, contains cocaine with sugar of milk, menthol and common salt.

The danger in using remedies containing cocaine consists in the liability to the formation of a cocaine habit. Instances have been cited in which persons purchasing this remedy have used a half-dozen bottles per day, with the result of producing permanent injury to health. According to the U. S. Dispensatory, the habitual use of cocaine "readily grows upon the individual, and the inveterate user can be recognized by his uncertain step, general apathy, sunken eyes, trembling lips, fetid breath, etc. Incurable insomnia is apt to be developed, emaciation becomes extreme, dropsy ap pears and even death results. Poisoning and even death have resulted both from its internal administration and its local use."

Kaskine, a much vaunted remedy, sold at one dollar an ounce, was found to consist of nothing but granulated sugar.

Modene, an empirical preparation for removing hair, was found to consist of calx sulphurata (sulphurated lime).

Ozonos, a proprietary disinfectant, was found to be a solution of permanganate of potash.

Information in regard to different brands of adulterated spices and other articles of food may be found in the twenty-first annual report of the Board (1889).

Names of brands of French peas colored with sulphate of copper (blue vitriol) were published in the weekly bulletin of May 9, 1891. That portion of the bulletin which contains the monthly food and drug report contains considerable additional information upon special subjects, which is published as occasion requires.

REPORTS OF THE ANALYSTS.

[621]

REPORTS OF THE ANALYSTS.

Dr. S. W. Abbott, Secretary of State Board of Health.

DEAR SIR: — I have the honor to present my report of the analysis of food and drugs for the year ending Sept. 30, 1896.

MILK.

From the beginning of the collection and examination of milk in 1883 under the food and drug acts to the present time there has been for the most part an annual increase in the number of samples reported. The past year shows a considerably larger number than ever before. For a number of years preceding the present the ratio of the samples of milk which were below the standard analyzed in this laboratory has varied but little from 50 per cent. The record of the present year, however, shows what may appear as a surprising improvement of quality, the samples below the standard amounting to only 35.2 per cent. of the total number analyzed.

But this improved ratio is due to the fact that the legal standard of total solids has been changed. For the months of July and August of the past year the legal standard of total solids was dropped from 13 to 12 per cent., so that a majority of the samples received during those months which under the old standard would have been reported adulterated are here reported of standard quality. Although the law now in force fixes the legal standard at 12 per cent. from April 1 to August 31, this law did not go into effect in time to include April, 1896, which is here reported under the 13 per cent. standard.

The tables show what might naturally be expected, that the percentage of adulteration of the samples collected from towns is considerably lower than in the case of milk from cities, while the milk from the "suspected producer" class is much the poorest of all.

Milk from Cities.

More artificially colored milks were found than usual. Forty-five samples proved to be thus sophisticated. They were collected in 14 towns and cities. Of these samples, 39 were colored with annatto and 6 with the aniline orange described in our report for 1895. Many of these colored milks were found to be above the legal standard in total solids. In one instance, in which a conviction was secured in court, the milk contained over 17 per cent. of solids. In this case the aniline orange was used, and the defendant admitted his guilt, urging as an excuse that his customers demanded a more highly colored article than natural milk.

Of the artificial colors, annatto seems to give a pale milk the most natural creamy appearance, and hence it is most extensively used. It is unfortunate for the milkman that when artificial coloring of any kind is used the yellow tint resulting is not confined chiefly to the cream, as is the case with the natural color of milk. It thus happens that when pure milk has stood for a sufficient time to allow the cream to separate, it is found on pouring off the top that the milk underlying the cream has the familiar bluish tint of "skimmed milk." But when an artificially colored milk is treated similarly, the yellow color is found to tinge the milk below the fat layer. In the regular course of analysis this appearance often directs the attention of the analyst to the artificial color, which is afterwards determined by the special tests.

No samples of milk were found to contain an added preservative. The use of formalin as a milk preservative, which is reported from some of the western States, has not been adopted here to any great extent.

A convenient means of detecting its presence in small quantities in milk is by the aid of fuchsine, decolorized by sulphurous acid.* Ten or twelve cubic centimeters of the suspected milk are treated with about 1 cubic centimeter of the decolorized fuchsine solution. After standing a short time, hydrochloric acid is added and the mixture shaken. The presence of formalin is indicated by a violet color, varying in depth according to the amount present. In the absence of formalin the milk shows only a yellowish color after shaking with the acid.

The accompanying table shows the results of the analysis of a series of milks of known purity from a herd of thirty-six cows,

^{*} Method of G. Deniges, "Jour. Pharm. et Chemie," ser. 6, 4 (1896, page 193).

chiefly grade Holsteins. This milk was taken during February, when the standard is 13 per cent. of solids. It will be seen that the average of the whole herd is materially below the standard.

Condensed Milk.

The analysis of a large proportion of the brands of condensed milk for sale in this State shows that for the most part a good quality of milk has been used by the manufacturers for this purpose. In a few instances, however, skimmed milk has evidently been used. This is clearly indicated by the low percentage of fat in the last few samples

[†] A mixture of 4 parts oats, 2 parts corn and 1 part wheat.

[‡] Hay very poor, not meadow.

[§] A mixture of 1 part corn ensilage and 1 part oat and pea ensilage.

in the accompanying table, in which the samples are arranged in the order of their fats. The ratio of fat to proteid of normal milk is something like 5 to 4, while in the last instance on the table it is shown as 1 to 5.

The so-called evaporated cream proves in most instances to be an ordinary grade of milk, evaporated to the consistency of cream without the addition of sugar. In one instance, however, as shown in the accompanying table, an evaporated skimmed milk appears as the favorite brand of "evaporated cream."

In the analyses here reported, the total solids, proteids and ash were determined by methods described in our report for 1895.

The determination of the fat has been made by a special method devised by Mr. A. E. Leach of this laboratory. It is well known to those who have tried to apply the Babcock method of fat deter-

mination to condensed milks which are preserved by the addition of cane sugar, that it is impossible to accomplish the clean separation of the fat, on account of the heavy char resulting from the action of the sulphuric acid on the sugar. No degree of dilution obviates this difficulty. To get rid of the sugar before applying the Babcock method, the following scheme was devised. Forty grammes of the sample are weighed out, and its aqueous solution is made up to 100 cubic centimeters in a graduated flask. Fifteen cubic centimeters of this solution, corresponding to 6 grammes of the sample, are withdrawn by means of a pipette, and are transferred to one of the large test bottles commonly used for skimmed milk determinations in the Babcock centrifuge. The capacity of the body of this test bottle is about 50 cubic centimeters, and its neck is graduated to read as fine as 0.1 per cent. Water is then poured in till the liquid nearly reaches the neck of the bottle, and 3.5 cubic centimeters of an aqueous solution of sulphate of copper is added, of the strength of 69 28 cubic centimeters per litre (Fehling's copper solution). The bottle is then well shaken and its contents are allowed to settle. The precipitate, which consists of proteids, carrying with it the fat, subsides more quickly if the bottle is set in ice water. The clear supernatant liquid, which contains the sugar in solution, is then drawn off by means of a small-stemmed pipette, of a capacity of 50 cubic centimeters, whose upper end is fitted for convenience with a piece of rubber tubing. A small wisp of absorbent cotton is lightly twisted about the lower end of the pipette, to serve as a filter. After the liquid is thus drawn up into the pipette the cotton wad is removed from its lower end by lightly rubbing it against the inside of the bottle's neck as the pipette is withdrawn. The precipitate is washed three times as above by decantation, and then 25 cubic centimeters of sulphuric acid are added, and the usual Babcock centrifuge method is followed. The reading to tenths, multiplied by six, gives the percentage of fat in the sample.

BUTTER.

The inspectors have been unable to find any case of oleomargarine substitution during the year; 349 samples were examined.

LARD.

Of 67 samples, 18 proved to contain added cotton-seed oil or tallow.

CHEESE.

No case of adulterated cheese has been found; 57 samples have been examined.

OLIVE OIL.

Of 33 samples, 10 were seed oil, either wholly or in part.

HONEY.

Of 65 samples, 10 consisted wholly or in part of glucose syrup. The poorest sample contained 75 per cent. adulteration.

MOLASSES.

Of 137 samples, 12 contained glucose syrup. The maximum adulteration was 70 per cent.

SYRUP.

All three of the refiners' syrups examined contained added glucose syrup.

MAPLE SUGAR.

Of the 22 samples examined, 7 contained notable quantities of crude cane sugar.

MAPLE SYRUP.

Of the 28 samples, 10 contained glucose syrup, or were chiefly sugar-house drips.

GROUND SPICES.

Allspice. — Of 129 samples, 6 were adulterated. The adulterants were ground fruit stones, wheat, ginger, nut-shells and peas. The worst specimen contained 40 per cent. of adulteration.

Cassia. — Of 250 samples, 7 were adulterated with ginger, wheat, sawdust and a foreign bark. The maximum adulteration was 50 per cent.

Cayenne again leads in respect of adulteration, 23 of the 67 samples proving to contain corn, wheat, turmeric, ginger or gypsum. The maximum adulteration was 50 per cent.

Cloves. — Of 235 samples, 10 were found adulterated with wheat, rice, allspice, ginger or clove stems. The maximum adulteration was 60 per cent.

Ginger. — Of 222 samples, 38 were found adulterated with corn or turmeric. The maximum adulteration was 70 per cent.

Mace. — Of 13 samples, 1 contained corn and turmeric.

Mustard. — Of 214 samples, 73 were found to contain turmeric, wheat, corn, buckwheat, rice, cayenne and potato. The maximum adulteration was 45 per cent.

Nutmeg. — Of the 12 samples examined, 1 contained wheat to the extent of 10 per cent.

Pepper. — Of the 337 samples examined, 22 were found to contain ground nut-shells, wheat, bark, ginger, olive stems or pepper hulls in large excess. The maximum adulteration was 65 per cent.

VINEGAR.

As usual, the percentage of adulteration in vinegar stands higher than any other food of which as large a number of samples has been examined. Of the 83 specimens submitted, 41 were below standard. The following table shows the analysis of these samples in detail:—

| Percentage of Acetic Acid. | Percentage of Solids. | Percentage of Acetic Acid. | Percentage of Solids. | Percentage of Acetic Acid. | Percentage of Solids. |
|----------------------------|-----------------------|----------------------------|--------------------------|----------------------------|-----------------------|
| | | | | | |
| | | | | | |

TEA.

Of 96 samples examined, only 1 proved to be adulterated.

COFFEE.

Of 120 samples examined, 16 were adulterated with chiccory, peas, wheat, dandelion, beans, sticks or gravel. The maximum adulteration was 70 per cent.

Cocoa (including Chocolate Preparations).

Of 39 specimens submitted, 9 of the samples of cocoa proved to be adulterated with rice, wheat, sugar, salt, oatmeal, arrowroot or potato. The sample containing the largest admixture showed but 44 per cent. of cocoa.

Confectionery.

Of 126 samples examined, only 3 were found to contain elements not properly edible. These were samples of chocolate lozenges, containing no chocolate, but colored with considerable addition of oxide of iron.

CREAM OF TARTAR.

Of 421 samples examined, 17 proved to be adulterated with corn, alum, gypsum or acid phosphate of lime. The poorest sample contained 70 per cent. of gypsum.

CANNED GOODS (exclusive of Condensed Milk).

Of canned goods, 47 samples were examined for metallic poison. Notable quantities of lead have not been found, and only 3 samples contained tin in injurious amount.

MISCELLANEOUS.

Of 190 samples classed under this head, 49 proved to be adulterated, or to contain injurious ingredients.

Among these samples were specimens of pickles, none of which were found to contain copper; of chowchow, which proved to contain salicylic acid, as also did samples of catsup and apple butter.

Samples of tripe and oysters were found to be preserved with boracic acid, and a sample of so-called "preservative" was found to consist of boracic acid.

Samples of extract of vanilla were found to be largely reinforced with coumarin.

Samples of "current jelly" were found to consist of apple jelly colored with cochineal.

Samples of tin foil used to wrap fresh cheeses and sausages were examined. The only sample which proved to contain more than 3 per cent. of lead, which is considered the danger limit in foil used for this purpose, was one in which was wrapped a cheese from Worcester County Creamery. This was a bright foil, in contrast to the dull foil used to wrap Neufchatel and cream cheeses. This specimen contained 52.8 per cent. of lead.

Samples of sausages were found to be colored artificially.

Summary of Food Statistics.

DRUGS.

Samples which do not conform with pharmacopæial requirements are here reported adulterated, or of poor quality.

Acetanilid: Of 21 samples examined, only 1 proved to be adulterated; it was found to contain corn.

Acidum Benzoicum: Of 6 samples examined, all were of good quality.

Acidum Hydrobromicum Dilutum: Of 7 samples examined, all were of good quality.

Acidum Tannicum: Of 5 samples examined, all were of good quality.

Æther: Of 22 samples examined, 4 were of poor quality, containing too much alcohol and water.

Alcohol: Of 14 samples examined, 4 contained too much water.

Aqua Ammoniæ: Of 7 samples examined, 3 were of poor quality, containing insufficient N H_3 .

Aqua Chlori: None of the 3 samples examined contained anywhere near the required amount of chlorine.

Aqua Destillata: Of 30 specimens, 25 were of poor quality. But very little care appears to be exercised by druggists to insure a good quality of this simple preparation. The subjoined figures will show the quality of the specimens examined. A pure distilled water of course contains no solid residue. The following figures indicate the parts of solid residue found in 100,000 parts of each sample:—

| 72 | 12 | 8 | 7 | 5 | 2.5 | 0 |
|------|------|-----|-----|-----|-----|---|
| 30 | 11.5 | 8 | 6.5 | 4.5 | 2 | 0 |
| 27 | 10 | . 7 | 5.5 | 4.5 | 1 | 0 |
| 14.5 | 10 | 7 | 5.5 | 4.5 | 0 | 0 |
| 12 | 9 | 7 | 5.2 | | | |

Aqua Hydrogenii Dioxidi: The single specimen examined seemed to be of pharmacopæial strength.

Argenti Nitras: Of the 16 samples examined, all were of good quality.

Bismuthi Subcarbonas: Of the 7 samples examined, all proved of good quality.

Bismuthi Subnitras: Of the 27 samples examined, 3 failed to meet the pharmacopæial requirements, containing traces of arsenic or notable amounts of subcarbonate.

Calx Chlorata: Of the 5 samples examined, none were of good quality, the amount of available chlorine being in one case but 5 per cent. of the requirement.

Calx Preparata: The 2 samples examined proved to be of good quality.

Cerii Oxalas: The 6 samples examined proved to be of good quality.

Chloral Hydras: The single sample examined proved to be of good quality.

Chloroformum: Of the 11 samples examined, 2 were of poor quality, containing too much alcohol.

Extractum Glycyrrhizæ: Of the 8 samples submitted, 7 proved to be adulterated with corn starch.

Extractum Nucis Vomicæ: All of the 3 samples examined were of insufficient strength, the percentage of total alkaloids being respectively 11.28, 10.92, 9.10.

Glycerinum: Of the eight samples examined, all were of good quality.

Hydrargyri Chloridum Mite: Of the 22 samples examined, all were of good quality.

Oleum Limonis: Of 10 samples examined, 4 were of poor quality, containing alcohol.

Paraldehydum: The single sample examined was of good quality.

Phenacetin: The two samples examined were of good quality.

Pulvis Opii: Of the 31 samples examined, 16 were not of pharmacopæial strength. The following figures show the percentage of morphine contained in the various samples:—

| 25.5 | 14.99 | 14.30 | 14.10 | 14.00 | 13.40 | 13.20 | 10.40 |
|-------|-------|-------|-------|-------|-------|-------|-------|
| 16.14 | 14.92 | 14.30 | 14.00 | 13.90 | 13.40 | 11.42 | 6.80 |
| 15.7 | 14.90 | 14.20 | 14.00 | 13.70 | 13.30 | 11.40 | 3.55 |
| 15.4 | 14.70 | 14.10 | 14.00 | 13.70 | 13.30 | 10.76 | |

Spiritus Ætheris Compositus: Of the 32 samples examined, only 7 proved of standard quality; 1 consisted chiefly of amyl alcohol, and the others contained little and in most cases no ætherial oil.

Spiritus Ætheris Nitrosi: Of the 13 samples examined, only 4 approximated the standard.

Spiritus Frumenti: Of the 13 specimens submitted, only 2 approached the standard requirements. The following table shows the results of analysis:—

| Percentage of Alcohol by Weight. | Percentage of Solids. | Percentage of Alcohol by Weight. | Percentage of Solids. | Percentage of Alcohol by Weight. | Percentage of Solids. |
|---|--------------------------------------|----------------------------------|------------------------------|----------------------------------|---------------------------|
| 44.18 43.52 43.14 42.95 42.29 | 0.00 0.65 0.70 0.23 0.79 | 40.70 39.80 39.00 38.22 | 1.20 0.66 1.00 0.20 | 37.78 37.11 35.50 31.62 | 0.70 1.50 0.66 0.46 |

Spiritus Juniperi: The single sample examined proved to contain too much water.

Spiritus Vini Gallici: Of the 2 samples examined, 1 was of poor quality.

Succus Limonis: Of the 2 samples examined, 1 was of poor quality, containing insufficient citric acid.

Syrupus: Of the 25 samples examined, 17 contained insufficient sugar.

No. 34.7

Tinctura Iodi: Of the 43 samples submitted, only 6 contained the required amount of iodine. The percentage of pharmacopæial requirement of iodine which these samples respectively contained is shown by the following figures:—

| 100 | 100 | 92 | 87 | 85 | 80 | 75 | 70 | 50 |
|-----|-----|----|----|----|----|----|----|----|
| 100 | 95 | 90 | 87 | 85 | 78 | 74 | 68 | 50 |
| 100 | 94 | 90 | 87 | 83 | 77 | 72 | 68 | 25 |
| 100 | 93 | 90 | 86 | 82 | 75 | 70 | 68 | |
| 100 | 92 | 88 | 85 | 80 | 75 | 70 | 67 | |

Tinctura Opii: Of the 58 samples examined, only 15 contained the required percentage of morphine. The respective percentages of morphine of these samples is indicated by the following figures:

| 2.02 1.51 | 1.33 1.27 | 1.16 1.16 | 1.09 1.09 | 1.03 1.03 | 0.93 | 0.88 | $0.45 \\ 0.18$ |
|--------------|--------------|--------------|--------------|----------------|--------------|----------------|----------------|
| 1.50 | 1.27 1.25 | 1.15 | 1.08 | 1.02 | 0.92 | 0.85 | |
| 1.49 | 1.22 | 1.12 | 1.06 | 0.99 | 0.91 | 0.76 | |
| 1.43 1.37 | 1.21 1.17 | 1.11 1.09 | 1.04 1.03 | $0.97 \\ 0.96$ | 0.90 0.89 | $0.56 \\ 0.51$ | |

Very many of these samples did not bear the red poison label and printed antidote directions, as required by statute.

Unquentum Hydrargyri: Of 8 samples examined, only 1 fulfilled the requirements of the pharmacopæia. The poorest specimen contained about half the requisite amount of mercury.

Vinum Album: Of 5 specimens examined, all were below the pharmacopæial standard, containing much added sugar.

Vinum Rubrum: Of the 12 specimens examined, all were below the standard. One specimen contained as much as 22.5 per cent. of solids, chiefly added sugar.

Miscellaneous.

Of 15 samples under this head, 5 were of poor quality.

In this class were included samples of face lotions, containing rose water, oxide of zinc, subcarbonate of bismuth, calomel, a trace of lead, salt, bay rum, prepared chalk, tincture of benzoin and a trace of corrosive sublimate.

Samples of sarsaparilla extract were examined, with the result of finding alcohol in the amount indicated in the accompanying table:—

| COMMERCIAL NAME OF SARSAPARILLA EXTRACT. | | | | | | | | | | | |
|--|--|--|--|--|--|--|--|--|-------|--|--|
| Ayer's Sarsparilla, | | | | | | | | | 21.00 | | |
| Thayer's Compound Sarsaparilla | | | | | | | | | 17.50 | | |
| Paine's Celery Compound, . | | | | | | | | | 17.00 | | |
| Hood's Sarsaparilla, | | | | | | | | | 15.25 | | |
| Green's Nervura, | | | | | | | | | 14.00 | | |
| Allen's Compound Sarsaparilla, | | | | | | | | | 10.92 | | |
| Dana's Sarsaparilla, | | | | | | | | | 10.92 | | |
| Brown's Sarsaparilla, | | | | | | | | | 10.85 | | |
| Corbett's Shaker Sarsaparilla, | | | | | | | | | 7.04 | | |
| Radway's Renovating Resolvent, | | | | | | | | | 6.36 | | |
| Moxie, | | | | | | | | | _* | | |

^{*} Mere trace.

The essential element of "Go to Sleep" was found to be sulphonal.

A face powder was found to consist of corn starch.

A so-called "Whiskey Salt" consisted of crude sodium carbonate.

A cleaning preparation called "Cuticlene" consisted essentially of corn meal, soap and nitro-benzol.

A sample of carbon dioxide gas, supplied in cylinders for soda fountain use, was found to contain 1.2 per cent. of air.

Respectfully submitted,

CHARLES P. WORCESTER.

WESTERN MASSACHUSETTS.

Comment has already been made, in previous reports, upon the superior quality of the milk furnished to consumers in the western counties of Massachusetts, as compared with that which is furnished to the population of the eastern part of the State. Two conditions or circumstances probably explain this fact. These conditions are very similar in character:—

First, the Density of Population. — In the four western counties the mean density of population, according to the census of 1895, was but little more than one-fourth as great as that of the remainder of the State, the exact ratio being as 116 to 399 (persons to the square mile). Other things being equal, adulteration of milk is more prevalent in densely settled than it is in sparsely settled districts. In densely settled districts the milk supply is derived largely from places at a considerable distance, and adulteration is more common in proportion to the distance of the producer from the consumer, and also to the time which elapses between production and consumption. In the cities and towns of the western counties the milk is produced within a few miles of the consumer, and is, therefore, of better average quality.

Second, Supply and Demand. — While the conditions of supply and demand are partially dependent upon seasons of the year, they are also closely connected with and dependent upon the former condition, — the density of population.

During the fourteen years which have elapsed since the food and drug acts went into operation, the Board has extended to the four western counties its regular and continuous inspection, in like manner with the eastern portions of the State; and, while the number of samples of milk inspected from this district has not been so great in proportion to the population at that of the eastern portion, it has been quite as great as the relative prevalence of adulteration in the two districts would seem to require.

The following is the list of cities and towns from which such samples of milk have been obtained, from 1884 to 1896 inclusive:—

Springfield.
Holyoke.
Northampton.
Chicopee.
Pittsfield.
North Adams.
Adams.
Greenfield.
Amherst.
Palmer.
West Springfield.

Montague (Turner's Falls).
Ware.
Westfield.
Lee.
Lenox.
Orange.
Shelburne.
Great Barrington.
South Hadley.
Deerfield.

The whole number of samples, and the number obtained in each year, together with the number found to be below the standard, are indicated in the following table:—

| Yea | YEARS. Samples of Milk. | | | | Number below Standard. YEARS. | | | | Number below Standard. |
|---|-------------------------|--|--|--|---|-------|--|---------------------------------|----------------------------|
| 1884, . 1885, . 1886, . 1887, . 1888, . 1899, . 1890, . | | | 163 281 126 219 299 300 270 326 | 52 49 25 23 47 53 61 60 | 1892, 1893, 1894, 1895, 1896, | tals, | | 252 187 183 245 157 | 50 38 39 60 27 |

The whole number of samples was 3,008, and of these 584, or 19.4 per cent., were not of standard quality.

This percentage (19.4) was less than half as great as that of samples taken in the eastern part of the State during the same time. It should, however, be stated that the conditions prevailing in the two districts are not exactly comparable, since a considerable number of the adulterated samples included in the total of those taken in the eastern counties was comprised of samples taken from suspected producers, and this class of samples usually presents a very high ratio of adulteration; while the demand for this line of inspection in the western counties has practically amounted to nothing, for the reason that the conditions of supply and demand have been such as

to present comparatively little inducement to fraud on the part of the producer. Still, if this class of samples were to be entirely eliminated from the comparison, there would still remain a very decided difference in the average quality of the milk furnished to consumers in the two districts.

The total number of prosecutions of offenders against the milk laws in this district during the period in question was 21, or an average of only $1\frac{1}{2}$ per year. Of this number, 16 resulted in conviction.

PROFESSOR GOESSMANN'S REPORT.

The whole number of samples of milk collected in the counties west of Worcester County during the year was 157, and the number found below the standard was 27, or 17.2 per cent. This is a lower ratio than that of any year since 1888, but this result is partly due to the change in the standard in certain months, as stated on a previous page.

The following summary embraces the samples of milk obtained during the year in cities and towns west of Worcester County.

The results of analyses were as follows: -

| Whole number examined, | | | | | | | | | 157 |
|----------------------------|-------|----------------|-------|---|---|---|---|---|------|
| | | • | | • | • | • | • | • | 130 |
| Number above standard, . | | ٠ | | | • | | | • | |
| Number below standard, . | | • | | | • | • | • | • | 27 |

CHARLES A. GOESSMANN.

A COMPARATIVE STUDY

OF THE

Toxin Production of Diphtheria Bacilli.

BY

Theobald Smith, M.D., and Ernest L. Walker.

1897.

INTRODUCTION.*

By Theobald Smith, M.D.

This inquiry was suggested by the following important problems bearing upon the restriction of diphtheria:—

- 1. Is there any difference in the pathogenic power of diphtheria bacilli from different localities?
- 2. Is the pathogenic activity of bacilli producing diphtheria in the summer season different from that of those producing disease in winter?
- 3. Is there any reduction in the pathogenic power of bacilli in cases in which they persist in the throat after recovery?
- 4. Are there any differences noticeable between the bacilli of mild and those of severe cases?

The third and the fourth questions have been attacked by other observers, while the first and the second have not been especially investigated. The answers to the third and the fourth questions have been, as a rule, negative. Observers have found little or no difference in bacilli from mild and severe cases, nor have they been able to show any recognizable loss of virulence in the bacilli persisting in the throat after recovery.

The reasons for entering upon this subject again were the opportunity we have had of examining cultures from different towns within the State, and more especially certain improved methods of cultivation by which the maximum toxin-producing capacity of each bacillus could be brought out and measured more accurately than had been done heretofore.

The selection of cultures for the study of the questions stated above has not been entirely satisfactory, mainly because much of the clinical information necessary to a proper choice was not accessible

^{*} The writer wishes to acknowledge the faithful assistance of J. R. Stewart, to whom the preparation of the culture media was chiefly entrusted. As will be seen from what follows, this so not a simple task.

at the time the cultures were received, and in some instances obtainable only with difficulty at the last moment when the final results were tabulated. We hope, however, that the material at hand may be supplemented by more in the near future.

THE MODE OF ACTION OF DIPHTHERIA BACILLI.

It is now a generally accepted theory that diphtheria bacilli act in the main through the toxins which they produce, and which are rapidly diffused into the fluids containing the vegetating bacilli. The contents of the bacilli themselves seem to be of little moment as pathogenic factors. Park and Williams * allowed the washed diphtheria bacilli to soak for a week "in a 0.5 per cent. alkaline carbolic solution." The injection of one cubic centimeter did not "produce any marked reaction in a 500-gramme guinea-pig," although the bacilli themselves were powerful toxin-producers. Kossel † collected the bacillar membranes from cultures, washed the bacilli repeatedly by centrifugalizing with 0.5 per cent. sodium chloride; then, after killing them with vapors of chloroform, he extracted them for several days in a few cubic centimeters of weakly alkaline fluids. The extract was only feebly poisonous, for it required 5 cubic centimeters to kill a 360-gramme guinea-pig in fortyeight hours.

Brieger and Boer ‡ found that shaking diphtheria bacilli with ammonium chloride and allowing them to stand for eighteen to twenty hours removes the toxin from the bodies of the bacilli. The bacilli after extraction were fatal to a 500-gramme guinea-pig, in doses of 0.01 gramme of bacillar substance. They acted by producing local necrosis. Brieger states that antitoxin had no effect upon this action of the dead bacilli, and that immunization towards it by gradually increasing doses failed. The poison itself withstood an hour's boiling.

These experimental observations, taken together, show that the toxin in the culture fluid and not the body substance of the bacilli themselves is to be looked upon as the disease agent. The success following the prompt application of antitoxin in sufficient doses is an additional support to this view. Moreover, the bacilli themselves do not penetrate into the body in large numbers, hence need not be specially considered as adding to the toxic effect of their products.

† "Deutsche Med. Wochenschrift," 1896.

We may, for convenience, regard the disease-producing power of diphtheria bacilli as made up of two elements, - toxicity and virulence. The former represents the rate of accumulation of toxin in culture fluids, and is easily measured; the virulence, on the other hand, which may be regarded as the behavior of diphtheria bacilli toward living tissue, is as yet an unknown quantity. This distinction between the toxic product of diphtheria bacilli and their inherent vital power to cope with living tissue seems to be established, at least experimentally, by the increase in virulence of diphtheria bacilli in their passage through a series of guinea-pigs, which has been reported by various observers. Thus, Aronson * states that a culture which was at first fatal to guinea-pigs of medium weight, in 0.1 cubic centimeter doses, was fatal, after some serial inoculations, in doses of 0.008 cubic centimeter. That is to say, its virulence was augmented twelve times. This experiment evidently means not that the toxin formed in the sub-cutis of guinea-pigs became twelve times stronger in quality at the end of the series, but that the bacilli injected were capable, by an adaptation of some sort, to multiply much more abundantly toward the end of the series, and hence produce more toxin. The other explanation, that the toxin itself had become more potent in quality, could only gain confidence if the bouillon culture produced much more toxin at the end of the experiment than at the beginning, the conditions remaining precisely the same.

To compare the disease-producing power of diphtheria bacilli from different sources, it was, therefore, thought best to study the relative accumulation of toxin in bouillon, and eliminate the bacilli by filtration before the test upon animals. The writer is fully aware of the fact that but an instrument of pathogenic power is here dealt with, and under artificial conditions, since we do not know the nature of the nutritive fluid which the bacilli make use of on mucous membranes, nor, as a consequence, whether the toxin production in bouillon is a true index of the production of toxin on mucous membranes. The problem is, in fact, very complex, as with all infectious diseases, and all we can hope to do at a time is to examine one factor of disease as carefully as possible, while eliminating all the others for the time being. The use of living cultures upon animals is of no service in these experiments, because it introduces at once three variable factors: (1) the bacilli as potential toxin-producers after

injection; (2) the poison of their bodies after destruction; and (3) the toxin pre-formed in the culture fluid injected. As a consequence, all who have used cultures find them uncertain in their action, as compared with the toxin alone. The bacilli injected as nearly free from fluid as possible are equally unreliable as measures of toxicity, as the following tests show:—

Two cultures of diphtheria bacilli are selected, which differ considerably in toxin-producing power, as is shown in Table I., where the toxin-producing power of one (No. 14) is about three times that of the other (No. 40). Inclined agar cultures are prepared from each, and after six days' growth the bacilli are removed with a platinum wire, the amount of moist bacilli weighed and stirred in 5 cubic centimeters sterile bouillon, making a moderately cloudy suspension. One cubic centimeter contained by weight about 0.0007 grammes of moist bacilli.

Bacillus No. 14. — Five-tenths cubic centimeter of the suspension, injected subcutaneously into a guinea-pig weighing 313 grammes, is fatal in five days; 1 cubic centimeter is fatal to a 330-gramme pig in six days.

Bacillus No. 40. — Of the suspension made in the way described, 1 cubic centimeter is injected into a guinea-pig weighing 315 grammes. Animal just escapes death, and is chloroformed on the sixth day. Another, weighing 330 grammes, receives 0.5 cubic centimeter. A slough forms at the place of injection. The guinea-pig remains in fair condition.

Though these tests show a greater activity on the part of Bacillus No. 14, yet we miss here not only the sharp definition in the results obtained by varying the dose of the same culture, but also in comparing the effect of the same doses of cultures from different sources.

A prolonged study of the relative production of toxin in bouillon under certain uniform conditions has shown such remarkably uniform results with the same culture, even after long intervals of time, that the results obtained in this way may be accepted as showing an inherent difference in the various bacilli studied.

THE METHOD EMPLOYED IN COMPARING THE TOXIN PRODUCTION OF DIFFERENT CULTURES.

In a former publication* the writer has given the conditions which must be fulfilled in order that a maximum accumulation of toxin may take place in bouillon cultures. The facts there considered and

^{* &}quot;Trans. Association American Physicians," for 1896.

others since then brought out may be very briefly reviewed here. In 1895 Spronck * called attention to the fact that the variable amount of sugar present in beef was responsible for the great fluctuations observed in the toxicity of diphtheria cultures. The writer had observed this independently of Spronck, by studying the relation between the amount of toxin in cultures and the amount of sugar as determined by the fermentation test. Sugar is present in all beef, but in perhaps 10 per cent. the amount is very small. In bouillon made from such beef the writer obtained very strong toxin. In bouillon from beef containing over 0.1 per cent. sugar the toxin was very feeble.

The cause for this difference lies in the acid or acids formed from the dextrose by the diphtheria bacillus, which inhibit the multiplication in a direct ratio to the amount formed. In sufficient quantity the growth may be entirely checked, and finally, when the acidity has reached a certain degree, the bacilli and the toxin are destroyed. Whether there are other causes at work besides mere inhibition of multiplication remains undetermined.

A small amount of dextrose, up to 0.05 per cent., is not inimical to toxin production; in fact, it seems to be more favorable than none at all, probably because a certain minimum amount is necessary for the cell life of the diphtheria bacilli. Bearing these facts in mind, we are better able to comprehend the various changes going on in cultures. The life of the culture begins with a rapid multiplication of the bacilli introduced and the formation of a surface membrane usually within twenty-four hours. At the same time, any sugar present is acted upon at once, with the result that the reaction becomes more acid. If the acidity increases beyond 2 per cent. of a normal acid solution, the culture is likely to become languid, the surface membrane rifted and settle to the bottom. Some bacilli, by a vigorous surface growth which probably oxidizes the acid products formed, may subdue a larger amount of acid, even to 3.5 per cent., and cause a rapid return towards the alkaline level. The toxin appears in greatest concentration when the alkaline level has been reached, usually within eight to twelve days when sugar is present in small amount only. When sugar is more abundant the acid. period is prolonged, during which little growth is evident. After

^{* &}quot;Annal. de l'Institut Pasteur," 1895, page 758.

[†] I. e., each 100 cubic centimeters of the culture fluid requires 2 cubic centimeters of a normal solution of alkali to bring the whole to the neutral point as determined by phenolphthallein.

several weeks a slow alkalizing tendency brings the culture to a more vigorous growth and to an alkaline reaction, but without much accumulation of toxin.

Without going into more detail on this subject, we may summarize the conditions under which diphtheria bacilli produce maximum amounts of toxin in the ordinary 1 per cent. (Witte) peptone bouillon as follows:—

- 1. Muscle sugar in the fluid from 0 to 0.05 per cent.
- 2. Initial reaction from 0.8 to 1.5 per cent. normal acid, the lower figure pertaining to bouillon containing the largest amount of sugar, the higher to bouillon containing none.
- 3. A thin layer of bouillon freely exposed to the air through one or more cotton-plugged openings in the vessel, and quiescent because the surface membrane which forms within twenty-four hours must not be disturbed.
- 4. The accumulation of toxin should be permitted to go on until the growth is checked by the alkaline reaction. This appears in from eight to twelve days, according to the initial reaction and amount of sugar present, and the growth ceases when the reaction is equivalent to 0.2 to 0.3 per cent. normal alkali.

The main difficulty before us, therefore, is to get beef containing only traces of dextrose. The writer's original plan, to select the bouillon in accordance with the fermentation test, is not feasible, because so little can be used. Spronck's suggestion, to allow the beef to lie for several days, in order that a partial decomposition by bacteria may transform the sugar, is better, but suffers from certain difficulties. The kind of bacteria cannot be controlled, and frequently the sugar is found but partially removed. Latterly, the writer has given up this method for one more rapid and certain in its action. The beef infusion is prepared either by extracting the chopped beef at 60° C. for several hours, or over night in the refrigerator. After removal of the beef the infusion is inoculated with a culture of some bacterium which rapidly acts upon dextrose, and placed in the thermostat over night. The writer has tried only B. coli, and found a complete transformation of carbohydrates taking place over night.

In the case of bouillon designed for diphtheria toxin the incubation should be as short as possible, so as to leave a trace of sugar in the fluid. This can be accomplished by placing the inoculated infusion in the thermostat at 10 P.M. and removing early next morn-

ing (8 a.m.). The infusion is then made up in the usual way, with 1 per cent. peptone, ½ per cent. sodium chloride. The final reaction should range, according to the amount of sugar left as stated above, between 0.8 and 1.5 per cent. normal acid, phenolphthallein being used as indicator. It can easily be brought to any desired point by adding from sterile solutions the calculated amount of normal acid or alkali (HCL or NaHO). The whole procedure is very simple after it has been put into routine practice. At any rate, the bacteriologist must make up his mind to give up the early slovenly methods of preparing culture media, or else be prepared for constant reverses and failures.

The bouillon must be sterilized finally in the autoclave, since the ordinary steaming frequently fails to destroy certain spore-bearing anaërobes, which begin to multiply after the diphtheria bacilli have formed a membrane and deoxidized the culture medium. These anaërobes inhibit the production of toxin.*

Park and Williams claim † that the amount of dextrose in beef purchased in New York City is not sufficient to interfere with the maximum accumulation of toxin if the culture be made sufficiently alkaline to begin with. This claim I cannot support by my experience with beef bought in the Boston markets. It may be that these authors had under observation bacilli which had acquired, through surface cultivation, a greater power to promptly oxidize acid products. This power is not possessed, as a rule, by bacilli recently isolated from the throat, with which this article deals.

A number of observers have published studies of the relative virulence of diphtheria bacilli from various sources, and those persisting in the throat after recovery for a variable length of time. It is not the object of this article to re-examine these writings and review the results obtained. For a summary of the literature the reader is referred to the article by J. H. Wright in the "Boston Medical and Surgical Journal," Vol. 131 (1894), page 329, and "Scientific Bulletin" No. 1 of the health department, city of New York (1895). A perusal of the various articles will show that the method of testing the virulence of the diphtheria bacilli was not adapted to give uniform or quantitative results. Thus, Park and Beebe, on page 23 of the

^{*} Since writing this, it has been observed that high temperatures in the autoclave may modify the bouillon in such a manner that only little toxin is formed subsequently. This matter is now under investigation.

^{† &}quot;Journal of Experimental Medicine," I. (1896), page 164.

bulletin referred to, recommend alkaline glucose bouillon as a culture medium, and the injection of cultures forty-eight hours old. Wright used sugar bouillon very largely. From what we now know of the inhibitory and destructive action of the acids formed from dextrose by diphtheria bacilli, the use of more than 0.1 per cent. dextrose in bouillon must be considered as at least unsafe. However, the authors followed general usage at that time, for even Escherich, in his work on diphtheria issued in 1894 (page 91), states that dextrose is not decomposed in appreciable manner by diphtheria bacilli, and therefore has no influence on growth.

Authors have not, so far as the writer knows, reported comparative tests of toxin production under conditions as nearly uniform as possible. It was mainly to fill this gap, if possible, that the series of cultures to be described were subjected to a comparative examination from the point of view of toxin production. Table I. gives a condensed account of the work done upon which the calculation of toxin production rests. In this table will be found: (1) the amount of acid produced in dextrose bouillon; (2) the condition of the bouillon used for the cultures; and (3) the test of the filtrate on guinea-pigs. The acid production will be dealt with farther on. The facts relative to the bouillon used need some explanation.

The beef used for bouillon, with one exception, was allowed to decompose according to Spronck's suggestion, but the results were not uniform, as stated above. In some of the bouillon the dextrose was absent, in some present in traces, in some in more appreciable amount, according to tests made with the fermentation tube and B. coli. In none was it present in the amount usually found in bouillon made from fresh beef. It is not probable that this slight fluctuation in the amount of dextrose had any appreciable influence on the culture. Where a doubtful result was obtained it was usually supplemented later on with a second test.

The question might be asked, Why not use the same bouillon for all bacilli studied, in place of the many lots actually employed? This would seem the simplest procedure, provided the bouillon did not change with time under the influence of light and air. A diminution in the amount of toxin produced in bouillon which had been standing for some time in a closet not absolutely dark had been casually observed. It is probable that bouillon in vacuo and kept in a dark place might meet the conditions of the problem, but bouillon kept under ordinary conditions would not. Further investigations

are now in progress to determine more precisely the degree of change produced in bouillon by age.

It might be claimed that different bacilli isolated from the throat would have different rates of growth in bouillon, and that the accumulation of toxin was simply a factor of the rate of multiplication, rather than of any inherent differences in the physiology of the bacilli. To answer this claim a determination of the number of diphtheria bacilli in cultures is not trustworthy, for the reason that diphtheria bacilli clump together, and the number of colonies in plate cultures may not indicate the number of bacilli used in preparing the plate. Again, bacilli may die in the course of growth, and others take their places. The writer has therefore endeavored to estimate the vigor of growth by the amount of change in the reaction produced. Cultures which in a given time in the same bouillon produce nearly the same amount of alkali may be regarded as having performed the same amount of work and grown with equal vigor. The uniformity of reaction in the various groups of bacilli studied together, after ten or twelve days, was such as to leave little doubt that the growth had been equally vigorous. When any culture lagged perceptibly behind, it was usually repeated with other bouillon.

The extent of the alkali production varies with the initial reaction of the bouillon and the presence of dextrose. Cultures containing the latter became at first more acid before swinging back to alkalinity. In Table I., therefore, it was deemed best to give both the initial reaction of the bouillon, the approximate amount of dextrose and the final reaction. Some idea may thus be gained of the amplitude of change which the fluid underwent during the period of growth permitted.

The culture vessel used at first was a large test tube placed in an inclined position after inoculation. This was soon given up for the Erlenmeyer flask, in which the depth of the bouillon was about 1.5 centimeters.

The toxin formed after ten to twelve days was tested upon guineapigs. The fluid was passed through filter paper until clear, then diluted with sterile salt solution, so that the quantity of toxin injected was contained in 1 cubic centimeter. Usually 0.1 cubic centimeter of toxin was injected. The place of injection chosen was the left side of the abdomen. Great care was exercised to deposit the fluid in the subcutis, and not to prick the muscles of the abdominal

wall. A vascular injection of the omentum or peritoneum is usually a result of the introduction of some of the fluid into the abdomen. When such reddening was noted at the autopsy, the test was repeated upon another animal, since death is hastened somewhat when this occurs. Guinea-pigs weighing between 300 and 350 grammes were used whenever possible. When larger ones had to be used, the increase in weight was duly taken into account.

From the results of such inoculations the minimum fatal dose upon a guinea-pig weighing 300 grammes was calculated. The calculation when such had to be made was based upon the fact that the minimum fatal dose usually kills a guinea-pig in from three and one-half to six If x represents this dose, then a guinea-pig which succumbed in two and one-half days, or sixty hours, received 10 x, and one which succumbed in thirty-six hours, $\frac{20 \text{ x}}{3}$. Guinea-pigs of greater weight do not necessarily bear an exact equivalent increase of toxin, but usually somewhat less. In general, it may be said that the values given as the minimum fatal doses may err within 10 per cent., owing to various factors which cannot be controlled. Among these is a slight variation among guinea-pigs in their tolerance of the virus, the darker (black, or black and red) animals being able to stand about 10 per cent. more toxin than the white animals. Even if we allow a variation of 10 per cent. in the values given in Table I., the general outcome of the comparative study is not made in any sense untrustworthy.

Comparative Study of Forty-two Cultures of Diphtheria Bacilli and of Four Cultures of Pseudo-Diphtheria Bacilli from Different Localities in Massachusetts.

By THEOBALD SMITH and E. L. WALKER.

MORPHOLOGY.

The following description of the morphology and the staining peculiarities of the bacilli studied is based on microscopic preparations from cultures of twenty-four hours' growth at 35° to 37° C. on Löffler's blood-serum mixture, uniformly fixed and stained. The cover-slip preparations were dried in open air at room temperature, fixed by heating twenty minutes in a dry-air sterilizer at the temperature of 120° C., and stained eight minutes with Löffler's alkaline methylene blue solution. It may be remarked, however, that experiment shows that the method of fixation has little if any effect on the outline of the bacillus or upon the aggregation of its chromatin, and consequently upon the irregularity of its staining.

In length the diphtheria bacilli vary from 1.5μ to 13μ , and for the purpose of description it is convenient to distinguish three groups: short bacilli, including all bacilli under 2μ in length; bacilli of medium length, including all bacilli between 2μ and 4.5μ ; and long bacilli, including all bacilli over 4.5μ in length. Bacilli in culture No. 33 are rather remarkable for their length, averaging 7.5μ to 10μ , while a few were found as long as 13μ .

It may be said of diphtheria bacilli in general that there appears to be a tendency for the shorter bacilli to become swollen at the middle and for the long bacilli to become swollen at the ends; and that the short bacilli are usually straight, while the long bacilli are usually curved or bent at an obtuse angle.

Comparison on the basis of length, outline and manner of staining allows the bacilli of the forty-two virulent cultures to be divided into three types, of which the following description may be given:—

Type I. - Bacilli of medium length, straight, cylindrical or slightly swollen in the middle, with blunt ends, and with intensely stained granules in an otherwise uniformly but less deeply stained cell. In the shorter bacilli of this type these granules are usually situated at the ends of the rod, one at each end; but in the longer bacilli there may be, in addition to these polar granules, one or more interpolar granules. These deeply stained bodies are usually of less diameter than the thickness of the bacillus, but may be of greater diameter, swelling the bacillus at the points where they are situated.

Type II. - Bacilli long, slender, curved, more or less swollen at one or both ends, and with alternating stained and unstained (or faintly stained) cross-segments.

Type III. — This includes seven of the forty-two cultures. are of various lengths, swollen in the middle, with tapering ends, and with broad, unstained terminal and intermediate segments. unstained terminal segments may be so extensive that a body simulating a nucleus in the middle of the cell is the only stained portion. More often the cell may consist of two stained and three unstained cross-bands. The staining of this type differs from that of Type II., in that the alternating segments of Type II. are narrow and numerous and the terminal ones are always stained.

Modifications of these types and intermediate forms occur even among bacilli of the same culture, but in nearly every case one form predominates sufficiently to allow the culture to be ranged under one of these three types. In the routine work of bacteriological diagnosis of diphtheria, as carried on under the direction of the State Board of Health, Type I. and its modifications are found in about 90 per cent. of the positive cases and bacilli of Type II. make up the greater part of the other 10 per cent. Bacilli of Type III. are very infrequently found. This classification holds good for young cultures on Löffler's serum mixture only.

Bacilli belonging to these three types have so far proved virulent to guinea-pigs when tested according to the methods given in another part of the text. But besides these a certain number of bacilli (Nos. 3, 4, 39 and 44 of the tables) have been isolated which are nonpathogenic, and which belong to the class of pseudo-diphtheria bacilli described farther on.

TOXIN-PRODUCING POWER.

The toxicity of the culture fluid of the forty-six cultures after an incubation at 35° C. for ten to twelve days ranged as follows, the 300-gramme guinea-pig being the basis of the computations:—

| | | | | C | Cubic Centimeters. |
|------------------------------------|---|--|--|---|-----------------------|
| In one the minimum fatal dose is | | | | | .03604 |
| In one the minimum fatal dose is | | | | | .045 |
| In five the minimum fatal dose is | | | | | .050 |
| In five the minimum fatal dose is | | | | | .060 |
| In four the minimum fatal dose is | | | | | .070 |
| In four the minimum fatal dose is | | | | | .075 |
| In eleven the minimum fatal dose i | s | | | | .080 |
| In two the minimum fatal dose is | | | | | .090 |
| In four the minimum fatal dose is | | | | | .100 |
| In five the minium fatal dose is | | | | | .120 |
| In four no toxin was formed. | | | | | |

Leaving aside for the moment the non-pathogenic forms, we notice in this summary, first of all, a considerable uniformity in the toxin-producing power. It is true the strongest toxin producer accumulates three times as much toxin as the weakest, but only one of such strength was found. It will be noticed also that the greater number of bacilli studied produce an 0.08 cubic centimeter toxin. If we group the cultures as follows,—

| | | | | C | ultures. | |
|---------------------------------|--|--|---|---|----------|--|
| .03606 cubic centimeter toxins, | | | | | 12 | |
| .07009 cubic centimeter toxins, | | | | | 21 | |
| .10012 cubic centimeter toxins, | | | , | | 9 | |

the predominance of the middle group is better brought out.

Cultures of much greater toxin-producing power have been isolated by Park and Williams. Of these, the minimum fatal dose is reported to range from 0.002 to 0.01 cubic centimeter. It is not stated whether these cultures produced this amount of toxin at the outset, or after periods of artificial cultivation.

By comparing these figures with the results of earlier observers, the greater efficiency of the method described appears in striking relief. Experimenters when first preparing antitoxin had some difficulty in finding bacilli whose toxin would yield a minimum fatal dose of 0.08 to 0.1 cubic centimeter. In the series here recorded only five out of forty-two fell below this mark.

Although the clinical records of the cases from which the bacilli came are very meagre, they suffice to show that any direct relation

between toxin production and severity of the disease is not obvious. This has been the inference of observers before us (Wright, Park and very recently Timaschew*), and we are able to confirm it after the application of more uniform and exact methods. This is what might be expected when we contemplate the complex nature of the disease process, the many factors which may enter into it, both on the part of the patient and the invading bacilli. There is one factor, for instance, which may modify the course of the disease, and therefore make any present-day estimates untrustworthy, -- namely, antitoxin. If applied early enough, it may convert a potentially serious case into a mild one, in spite of a virulent organism. Antitoxin was used in nearly every case from which bacilli were studied, but the time of administration and the number of units injected were not reported excepting in a few cases, so that the facts on hand are not worth any serious study. All that can be said is that the toxinproducing power of bacilli from mild and from severe cases varies but little, and that all throat affections must be regarded equally dangerous if diphtheria bacilli are present.

THE TOXIN-PRODUCING POWER OF BACILLI PERSISTING IN THE THROAT AFTER RECOVERY.

Much interest has been aroused by the patients in whose throats diphtheria bacilli may be found a variable length of time after subsidence of all symptoms of disease. Löffler, in his investigation of the ætiology, found diphtheria bacilli in the throat of a healthy child. Roux and Yersin first called attention to the persistence of diphtheria bacilli after recovery, but they disseminated the impression that there was a gradual attenuation going on which eventually made them harmless. That this may be true in certain cases is not disputed, otherwise it would be difficult to account for the presence, in the mouth of some healthy persons, of bacilli in no way distinguishable from those associated with disease processes except by an absence of virulence.† This attenuation has not been observed by subsequent investigators, however, and no reliance can be placed upon it to purge the throat of the recovered case of its infectious character.

Among the forty-six cultures studied there were eleven made from the throat fifteen to sixty-two days after the appearance of the dis-

^{* &}quot;Centralblatt f. Bakteriologie," XXI. (1897), page 623.

[†] Park and Beebe, loc. cit., page 37.

ease. Owing to the meagre records returned, it is impossible to state how long after the subsidence of the symptoms the bacilli were obtained from the throat; but by a reference to Table II., where the relative severity of each case is noted, some idea may be gained by the reader of the probable duration. The following table summarizes these cases. It includes two from which harmless pseudoforms were obtained:—

| | Numi | BER OF | CULTU | JRE. | Date of Earliest Symptoms. | Date of Culture. | Interval (in Days). | Minimum Fatal Dose of Toxin (Cubic Centimeters). |
|-----|------|--------|-------|------|-------------------------------|------------------|---------------------------|--|
| 23, | | | | | July 12, 1896. | Aug. 3, 1896. | 22 | .07 |
| 24, | · | | | | July 14, 1896. | Sept. 9, 1896. | 57 | .08 |
| 26, | | | | | Aug. 28, 1896. | Oct. 19, 1896. | 52 | .05 |
| 27, | | | | | Sept. 27, 1896. | Oct. 19, 1896. | 22 | .06 |
| 34. | | | | | Oct. 22, 1896. | Nov. 17, 1896. | 26 | .05 |
| 36, | | | | | Nov. 15, 1896. | Nov. 30, 1896. | 15 | .08 |
| 39, | | | | | Nov. 22, 1896. | Dec. 29, 1896. | 37 | Not toxic. |
| 40, | | | | | Dec. 18, 1896. | Jan. 4, 1897. | 17 | .12 |
| 42, | | | | | Dec. 31, 1896. | Jan. 16, 1897. | 16 | 07 |
| 43, | | | | | Feb. 20, 1897. | March 19, 1897. | 27 | .08 |
| 44, | | | | | Feb. 8, 1897. | March 25, 1897. | 45 | Not toxic. |
| 45. | | | | | Feb. 9, 1897. | March 23, 1897. | 42 | .08 |
| 46, | | | | | Jan. 29, 1897. | April 1, 1897. | 62 | .08 |

If we exclude the harmless, non-toxic cultures (Nos. 39, 44), which will be discussed farther on, we observe that, so far as toxin production is concerned, the length of time the bacilli have sojourned in the throat has no tendency to reduce it below the average. This is still better brought out by arranging the cultures in the following groups:—

| | | Group | ٠. | | Days after Beginning of Disease. | Number of the Culture. | Toxicity (Cubic Centimeters). |
|-------|---|-------|----|---|--|---------------------------|-------------------------------|
| I., | • | | | ٠ | 15 to 20 { | 35 40 42 | .08 .12 .07 |
| II., | | | | ٠ | 20 to 30 { | 23 27 34 43 | .07 .06 .05 .08 |
| III,. | | ٠ | | • | 50 to 62 | 24 26 45 46 | .08 .05 .08 .08 |

Still more to the point are cultures Nos. 22 and 23, which were isolated from the same case, one three, the other twenty-two, days after the onset of the disease. Here the toxin production was practically the same for both cultures.

PSEUDO-DIPHTHERIA BACILLI.

From the table it will be seen that four of the forty-six cultures isolated were found to be pseudo-diphtheria bacilli. It does not lie within the scope of this paper to discuss at length the relation between the true diphtheria bacillus and the pseudo-diphtheria bacillus. A very good discussion will be found in the work of Park and Beebe, to which the reader is referred. Since its appearance nothing new has been added to this subject. These bacilli, however, influence to a certain degree the interpretation of problems in public sanitation, so that a brief reference to them becomes necessary.

These bacilli, generally known as pseudo-diphtheria bacilli, are short rods (1.5 μ to 3 μ), with rounded or tapering ends (often oval in culture), and uniformly stained, or with a single narrow, unstained cross-segment. A few cylindrical, pear and hour-glass shaped bacilli are occasionally seen; but involution forms are not marked, even in old cultures. They are distinguished from diphtheria bacilli by being shorter, smaller, more uniform in size, shape and manner of staining, and, as pointed out by Escherich, by a tendency to lie parallel in cover-slip preparations. These bacilli are of occasional occurrence, both in the throats of patients suffering from non-diphtheritic throat affections and in true diphtheria mingled with the Klebs-Löffler bacilli. They are, however, almost always present in small numbers, while the diphtheria bacilli, in recent cases, are usually present in large numbers and well differentiated. It is only in convalescent cases of long duration that the pseudo-diphtheria bacilli are likely to cause doubt. They might be mistaken for the last few remaining diphtheria bacilli, or the reverse might occur. A few remaining virulent forms may be regarded as pseudo-forms. Diphtheria bacilli directly from the membrane from the throat, or from cultures scarcely at all developed, sometimes resemble quite closely the pseudo-diphtheria bacilli in morphology and staining.

The morphological differences are reinforced by at least two biological differences of importance,—the absence of any power to produce acids in bouillon containing dextrose, and the lack of

pathogenic power. In Table I. it will be seen that all toxin-producing bacilli, when multiplying in bouillon containing 1 per cent. dextrose, produce a considerable amount of acid, ranging from 3.5 to 5 per cent. of a normal acid solution when phenolphthallein is used as an indicator. A few cultures were found which produce between 5 and 6 per cent. The pseudo-diphtheria bacilli produced no acid under the same circumstances. The culture slowly becomes more alkaline, as shown in the table (Nos. 3, 4, 39, 44). The culture fluid of these bacilli was likewise free from toxin. Guineapigs which received from six to twelve times the average fatal dose of the virulent cultures showed no trace of infiltration at the place of injection and no loss in weight.

Though there are these three distinctive features of pseudodiphtheria bacilli, - characteristic morphology, absence of acid and of toxin production, - it is not a simple matter to recognize them as such promptly under the microscope when taken from throat cultures, unless the observer has had considerable training. It is highly probable, therefore, that Roux and Yersin in their earlier work may have mistaken pseudo-diphtheria bacilli for true diphtheria bacilli, when they found virulent and non-virulent forms together in the throats of convalescents. This may explain their at that time quite natural position, - that the virulent forms were being transformed into non-virulent forms. In two of the cases tabulated above (Nos. 39 and 44) the pseudo-diphtheria bacilli were isolated respectively thirty-seven and forty-five days after the beginning of the disease. Here, without a more profound study of the cultures, the belief might gain the upper hand that the cultures represented diphtheria bacilli which had lost their virulence. This position can no longer be upheld, and we must accept or at least act upon the presumption that the pseudo-diphtheria bacilli belong to a wholly different group of bacilli, and that a loss of pathogenic power of the genuine forms does not take place in the mouth for months after the subsidence of the disease, when such forms persist after recovery.

Of the non-virulent but otherwise characteristic diphtheria bacilli, described by Park and Beebe and by others more recently, none have come under observation.

TABLE II.

| | Bacilli of medium length, cylindrical or slightly swollen | in the middle, and with deeply standed granules. Bacilli of medium length, rather thick, cylindrical or slightly swollen in the middle, and with deeply stained | granules. Bacill short (about 2μ), with rounded or tapering ends, and with a single unstained or faintly staned cross- | segment. Bacilli short (from 1.5 μ to 2 μ), oval, evenly stained, or | with a single very dirrow instance orons-segment. Baoilli of varions lengths, with tapering ends or variously swollen, and with large unstained terminal and interme- | mediate segments. Bacili rather below medium length, considerably swollen in the middle, many being with tapering ends, and with | large unstained terminal and intermediate segments. Baclli of medlum length, with tapering ends, and with natiated terminal and intermediate segments: a few | cylindrical forms with deeply stained granules Baellli rather long, slender, cylindrical or with slightly | swonen ends, and witn deeply stanged point grannivs. Bacilli of medium length, or long bacilli, that are cylin- drical or with slightly swollen ends and with alterbat. | ing stained and unstained cross-segments. Bacilli of medium length, with tapering ends, and with a | stance interesting boay in a once we concrete call. Bacilli of medium length, straight, cylindrical or slightly swollen in the middle, and with deeply stained polar | granules. Bacili of medium length, or long bacilli, that are cyllndreili or with slightly swollen ends, and with alternat- | ing stained and unstained cross-segments Bacilli rather short, plump, with papering ends, and with | unstance termina and mermenate segments. Bacilli rather long, slender, curved, cylindrical or with slightly evollon onds and with alternating status and | faintly stained cross seements. Bacilli of medium length, cyllndrical or slightly swollen in the middle, and mostly evenly stained. |

REPORT

UPON THE

PRODUCTION AND USE OF ANTITOXIN.

[673]

REPORT

UPON THE

PRODUCTION AND USE OF ANTITOXIN,

FOR THE

TWELVE MONTHS ENDING MARCH 31, 1897.

This second report upon this subject is intended to present the practical details of the work of the Board in this direction for the space of one year, following immediately after the termination of the first summary presented in the last annual report. The unavoidable delay in publishing the annual reports, which contain accounts of the general work of the Board for the different years of official work, permits the extension of the time of this portion up to the first of April. Another reason for this method of presentation exists in the fact that the Board began the first distribution of its antitoxin at that season of the year (about April 1, 1895).

The general supervision of the production of antitoxin for the Board throughout the year has been in charge of Dr. Theobald Smith, assisted by J. R. Stewart, and the work has been performed at the bacteriological laboratory of the Board, at the Bussey Institute. The minor details of the work (labelling, packing, mailing, recording and correspondence) have been performed at the office of the Board, at the State House.

The strength of the serum issued during the year embraced in this report was maintained substantially at a uniform standard of 100 units per cubic centimeter.

A considerable quantity of a weaker serum, having a strength of 60 to 80 units per cubic centimeter, has also been prepared and furnished for use to such authorities as have desired it for the purpose of immunization only.

During the early part of 1895 the Board had issued antitoxin to the Boston City Hospital for use in its contagious disease department, but this demand ceased as soon as the city board of health began issuing antitoxin.

That the use of antitoxin is steadily increasing and that this therapeutic agent is growing in favor among physicians is shown by the fact that the number of packages issued by the Board has nearly doubled, when the figures of 1896 are compared with those of 1895. Nor is this due to an increase in the prevalence of diphtheria during these two years, since the returns of deaths received at the time of writing this report indicate a lessened mortality from this cause.

It is to be regretted that the returns of cases treated by physicians are very much smaller in number than the actual number of cases treated, the ratio of returns to cases treated being even less than that of 1895, if the number of bottles issued is an indication of the number used. The statements as to the probable cause of this deficiency, which were published in the last annual report, are quite as applicable to the conditions prevailing in 1896.

The total amount of diphtheria antitoxin issued by the Board during the year ended March 31, 1897, was 3,245 bottles, containing in all about 35,000 cubic centimeters of serum, nearly all of which was of a uniform strength of 100 units per cubic centimeter. This serum was distributed to local boards of health and to physicians in the following cities and towns:—

CASES IN WHICH A BACTERIAL EXAMINATION WAS MADE.

Following the same method of classification which was adopted in the report of the previous year, the cases in which cultures were made are classified into those which proved on examination to be cases of genuine diphtheria and those which did not; in other words, into positive and negative cases.

Diagnostic examinations by means of culture were made in 205 of the cases reported, and of these, 189 proved to be cases of genuine diphtheria and 16 gave a negative result.

Positive Cases.

Of the 189 cases, there were 167 recoveries and 22 deaths, or 11.6 per cent., — a slight improvement over the results of the previous year, which was 13.7 per cent.

Sex. — The number of males was 76 and the deaths of these were 11, or 14.5 per cent., which was almost identical with the 14.4 per cent. of the previous year. The females were 109, and the deaths of these were 9, or 8.9 per cent., as compared with 12.6 per cent. in 1895. The sex of four was not stated. Two deaths.

Ages. — The following table presents the cases and deaths by ages: —

Year ending March 31, 1897.

| Ac | E P | ERIODS | Cases. | Deaths. | Fatality (Per Cent.). | | | |
|---|-----|--------|--------|---------|-----------------------|--------------------------------------|-----------------------|------------------------------------|
| From 0 to 2 years, From 2 to 5 years, From 5 to 10 years, Over 10 years, Age unknown, | : | : | | : | : | 17 63 47 60 2 189 | 3 9 7 3 0 | 17.6 14.3 14.9 5.0 0.0 |

Of those who were more than ten years of age, 33 were between ten and twenty, 16 were between twenty and thirty, 6 were between thirty and forty, 3 were between forty and fifty, 1 was 58 and 1 was of unknown age. Of the fatal cases in this class, 1 was eleven, 1 was twenty-three and the remaining 1 was forty-three years old.

Day of Illness when Antitoxin was first administered. — The following table presents the fatality, according to the day of illness on which antitoxin was first administered: —

| | Da | Υ. | | Cases. | Deaths. | Fatality (Per Cent.). 1896. | Fatality (Per Cent.). 1895. |
|--|--------|----|-------|--|---------------------------------|--|--|
| First, Second, Third, Fourth, Fifth, Sixth, Seventh, Eighth a | i i | b | • | 22 42 36 22 6 7 4 6 | 0 4 3 5 0 1 1 | 0.0 9.5 8.3 22.7 0.0 14.3 25.0 16.6 | 0.0 9.7 8.7 15.4 22.2 20.0 33.3* |

* Seventh day and later.

This table relates only to those cases in which a definite statement is given as to the day on which the antitoxin was first employed.

The small numbers in the lower part of this table have but little significance as compared with the larger numbers. They are retained, however, with the hope that the grouping of several years' experience will prove more valuable.

Fatality in Hospital and in Private Practice.—The fatality of the positive cases treated in hospitals was as follows: cases, 39; deaths, 2=5.1 per cent. In private practice: cases, 150; deaths, 20=13.3 per cent.

Seasons of the Year. — The cases embraced in the foregoing enumeration occurred in the following order:—

| | Mox | тнз. | | Cases. | Deaths. | Mox | THS. | | Cases. | Deaths |
|---------|-----|------|--|--------|---------|-----------|------|--|--------|--------|
| | 18 | 96. | | | | | 96. | | | |
| April, | | | | 7 | 2 | October,. | | | 24 | 4 |
| May, | | | | 5 | 1 | November, | | | 27 | 2 |
| June, | | | | 5 6 | 0 | December, | | | 25 | 0 |
| July, | | | | 10 | 1 | | | | | |
| August, | | | | 8 | 0 | 18 | 97. | | | |
| Septemb | | | | 11 | 2 | January, | | | 28 | 3 |
| 1 | , | | | | | February, | | | 19 | 3 |
| | | | | | | March, . | • | | 19 | 4 |
| | | | | 47 | 6 | | | | 142 | 16 |

By this table it appears that there were 47 cases and 6 deaths among positive cases in the warmer months, and 142 cases with 16 deaths in the colder months.

Negative Cases.

The number of cases in which a negative result was obtained was 16. Two cases were excluded from the full number of 18 and placed in the group of positive cases, where the history and the clinical statement clearly indicated genuine diphtheria. There was also one case in which a negative result was obtained, in which the package, through the carelessness of an expressman, was frozen in its transit to the State House. There were no deaths among these 16 negative cases.

SUMMARY OF THE TWO YEARS, ENDING MARCH 31, 1897.

Positive Cases treated with Antitoxin.

Whole number for the two years, 451; deaths, 58; fatality, 12.8 per cent.

Sex. — The fatality by sexes was as follows: —

| | | | | SEX. | | | | | | Cases. | Deaths. | Fatality (Per Cent.). |
|----------|---|---|---|------|---|---|---|---|---|--------|---------|--------------------------|
| Males, | | | | ٠ | | | | | | 201 | 29 | 14.4 |
| Females, | ٠ | • | • | • | ٠ | • | ٠ | • | • | 244 | 26 | 10.9 |

The sex of six was not stated.

Ages. — The fatality by ages was as follows: —

| | | Age | PERIO | DDS. | | | Cases. | Deaths. | Fatality (Per Cent.). |
|---|---|-----|-------|------|---|------|------------------------------|--------------------------|------------------------------------|
| ′ | : | • | • | | : | | 47 134 138 127 5 | 12 25 16 5 0 | 25.5 18.7 11.6 3.9 0.0 |

Hospitals and Private Practice.

| | | | | | | Cases. | Deaths. | Fatality (Per Cent.). |
|---------------------------------------|---|---|---|---|--|-------------------|----------|-----------------------|
| In hospitals, In private practice, | : | : | : | : | | $\frac{124}{325}$ | 17 41 | 13.7 12.6 |

CASES IN WHICH NO BACTERIOLOGICAL EXAMINATION WAS MADE.

Reports were made of 268 cases where antitoxin was employed, in which no cultures were taken. Out of this number there were 30 cases which proved fatal, or 11.2 per cent. of the whole. This number differs but little from that of 1895 for the same class of cases, that of 1895 having been 11.7 per cent. There were, however, 3 of the cases which occurred in this class in 1896 which may properly be rejected from consideration, since the patient was at the point of death in each case at the time of administration of the antitoxin. The following terms were employed in the returns in describing these cases: "moribund," "comatose," and "dying at the time of administration." It would, therefore, be proper to reject such cases as being beyond the power of remedial agencies of any sort. The rejection of these 3 cases, therefore, would reduce the number of cases to 265 and the deaths to 27, or 10.2 per cent.

Sex. — The number of males in this class was 111 and the deaths of these were 14, or 12.6 per cent. The number of females was 142 and the deaths of these were 13, or 9.2 per cent. The number of those whose sex was unknown or not stated was 12, and there were no deaths of these.

Ages. — The following table presents the cases and fatality by ages: —

| AGE | PERIO | DB. | | | Cases. | Deaths. | Fatality (Per Cent.). |
|-----|-------|-----|---|---|---------------------------|------------------------|-----------------------------------|
| : | : | • | • | : | 28 83 88 62 4 | 3 15 5 4 0 | 10.7 18.1 5.7 6.5 0.0 |

Of those who were over ten years old, 41 were between ten and twenty years, 10 were between twenty and thirty, 7 were between thirty and forty, 2 were between forty and fifty, 1 was sixty and another was seventy-three.

Day of Illness when Antitoxin was first administered.

The cases and deaths, distributed according to the day of illness when antitoxin was first administered, are presented in the following table:—

| | Day of | Illness | when | Antitoxin | was | first | administered. |
|--|--------|---------|------|-----------|-----|-------|---------------|
|--|--------|---------|------|-----------|-----|-------|---------------|

| | | DAY. | | | Cases. | Deaths. | Fatality (Per Cent.) |
|---|-------|------|------|------|---|------------------|---|
| First, . Second, Third, Fourth, Fifth, . Sixth, . Seventh a Unknown | ater, | | | | 40 54 25 27 11 9 12 87 | 1* 2 3 6 2 2 5 6 | 2.5 3.7 12.0 22.2 18.2 22.2 41.7 9.0 |

This fatal case was that of a man thirty years of age, and of extremely intemperate habits.
 The reporter states that, in his opinion, the man would have recovered if it had not been for this fact.

Of the cases in which the administration was delayed until the seventh day or later, the antitoxin was used on the seventh day in 4 cases, on the eighth in 4, on the ninth in 1 case, on the tenth in 1 and on the fifteenth in 2 cases.

Hospitals and Private Practice.

The fatality among the private and hospital cases of this class was as follows:—

| | | | Cases. | Deaths. | Fatality (Per Cent.). |
|---|---|---|--|---------|-----------------------|
| Treated in hospitals, Treated in private practice, | • | : | $\begin{array}{c} 43 \\ 222 \end{array}$ | 2 25 | 4.7 11.3 |
| | | | 265 | 27 | 10.2 |

SEQUELÆ.

In this summary all cases are considered together, those in which cultures were made and those in which none were made.

Eruptions. — Urticaria was reported as occurring in 60 cases, of varying severity and at greater or less intervals from the time of administration of antitoxin. In 16 cases it was noted as "slight," or at point of injection only; in 10 cases it was "copious," or generally distributed over the body; and in the remainder its severity was not specified. In several cases it appeared as early as the third or fourth day, and in 1 it was delayed till the eighteenth and in another till the twentieth day. It usually lasted from two to five days.

Albuminuria was reported in 51 cases. In 20 it was reported as "slight," or a "trace" only; in 3 it was severe, and attended with a fatal result; and in the remainder the character was not stated.

In 9 cases rheumatic pains and joint affections were reported.

In 9 cases paralysis of the throat was reported and in 2 paralysis of the legs.

OPERATIONS.

Of the foregoing cases, there were 22 in which operative interference was deemed necessary, and of these there were 17 in which intubation was performed, all of which recovered except 1. Nine of these were females, 7 were males and the sex of 1 was not stated. Their average age was three years and eleven months. One of these was intubated on the second day of illness, 2 on the third, 3 on the fourth, 4 on the sixth (1 fatal), 3 on the seventh, 1 on the eighth, and the time was not stated in 3 cases.

Tracheotomy was performed in 5 instances, 2 of which were fatal. All were females. One was two and one-half, 2 were four, another five, and the fifth was forty-three years old, and in the case of this adult the result was fatal.

THE BRANDS OF ANTITOXIN EMPLOYED.

Since this report deals mainly with the antitoxin produced and offered for use to the local boards of health by the State Board of Health, it follows that the returns received upon the blank forms supplied by the Board present the results of its use. In a few instances, however, returns were received from parties who had, through inability to obtain the product supplied by the Board, or for other reasons, employed other brands, and in some cases two different brands were used in the treatment of single cases.

DEATHS.

Private Practice.

- 1. Male, two years, two months (April, 1896). Weak and rapid pulse, 132; great prostration; membrane over tonsils and pharynx; hoarseness, dyspnœa and stenosis; glands normal. Antitoxin administered, 5 cubic centimeters; time not stated.
- 2. Male, five years (May, 1896). Temperature, 99°; pulse, 132, strong; condition at onset of illness excellent; membrane on posterior wall and left tonsil; hoarseness, cough, dyspnæa and stenosis; glands slightly enlarged; difficult breathing on fifth day. Antitoxin, 10 cubic centimeters; time not stated.
- 3. Female, eleven years (July, 1896). Temperature, 105°; pulse, 160, fairly strong; restless, weak and delirious; membrane on both tonsils, and increasing; neck glands swollen; all symptoms progressively worse. Antitoxin, 18 cubic centimeters, second day; 9 cubic centimeters, third day.
- 4. Male, seven years (September, 1896). Temperature, 101°; pulse, 140, weak; cyanotic; pale; prostration; membrane on posterior wall of pharynx, right tonsil, side of uvula and in the nose, and spreading; stenosis of larynx; copious epistaxis. Antitoxin, second day, 10 cubic centimeters in morning, 10 in afternoon and 10 on third day. Death on fourth day.
- 5. Female, eight years (September, 1896). Temperature, 102.5°; pulse, 100; patient irritable; membrane on both tonsils and part of soft palate; slight dyspnœa; right parotid gland enlarged; urine albuminous. Antitoxin, 7½ cubic centimeters. Death, thirteenth day.
- 6. Male, two and one-half years (October, 1896). Temperature, 99½°; pulse, weak; moderate prostration; membrane on tonsils and uvula;

hoarseness and cough; neck glands enlarged. Antitoxin, 5 cubic centimeters, sixth day; 5 cubic centimeters, seventh day. Death on ninth day.

- 7. Male, three years, two months (October, 1896). Temperature, 102°; pulse, 110, strong and regular; membrane on tonsils and fauces; hoarseness and cough; neck glands swollen, tender and tense; extreme prostration. Antitoxin (Behring's), 3 cubic centimeters, fourth day; 1 cubic centimeter (State Board of Health), fifth day, morning, 5 cubic centimeters, afternoon; 5 cubic centimeters, morning, sixth day. Death on seventh day.
- 8. Female, eleven months (October, 1896). Temperature, 105.2°; pulse, 80-180, weak; general condition poor; membrane on posterior wall, densely covered; dyspnæa and stenosis. Antitoxin, 6 cubic centimeters, repeated once; time not stated.
- 9. Male, five years (October, 1896). Temperature, 104°; pulse, 144; severe prostration; membrane in nose; hoarseness, cough, dyspnæa and stenosis; neck glands on left side much swollen; urine slightly albuminous. Antitoxin, 10 cubic centimeters, third day; 10 cubic centimeters, fourth day; 10 cubic centimeters, fifth day. Hemorrhages from mouth and nose on sixth day. Death on sixth day.
- 10. Male, four years (November, 1896). Temperature, 102°; pulse, 160, weak; severe prostration; neck glands enlarged; stenosis. Antitoxin, 600 units, morning, fourth day; 600, afternoon, fourth day; 600, sixth day. Death, eighth day.
- 11. Male, twenty-three years (November, 1896). Temperature, 103°; pulse, 120; great prostration; membrane on tonsils and palate; hoarseness, cough and dyspnœa; neck glands swollen. Antitoxin, 1,200 units, third day; 600, fourth day. Death, fifth day.
- 12. Female, five years (January, 1897). Temperature, 102°; pulse, 120, weak; membrane over tonsils and pharynx; hoarseness, cough, dyspnœa and stenosis; neck glands swollen. Antitoxin, two doses, 10 and 5 cubic centimeters; time not stated. Death thirty-six hours after first visit.
- 13. Male, eight years (January, 1897). Temperature, 103°; pulse, 90-132, regular and strong; great prostration; membrane on tonsils, uvula and soft palate and in the nose; slight stenosis; neck glands moderately enlarged. Drowsy, vomiting, and finally collapse and death on seventh day. Antitoxin, 4 cubic centimeters, morning, fourth day; 3 cubic centimeters, afternoon, fourth day; 3 cubic centimeters, fifth day; 5 cubic centimeters, sixth day.
- 14. Female, forty-three years (February, 1897). Pulse, weak; great prostration; very anemic; hoarseness, cough, dyspnæa and stenosis; urine pale, specific gravity 1,006, acid, trace of albumin, casts, puss and cells. Tracheotomy. Antitoxin, 1,000 units, fourth day; 1,000 units, fifth day; 1,000 units, seventh day. Death, ninth day.

- 15. Female, two years, ten months (February, 1897). Temperature, 97°; pulse, 80, very weak; marked toxemia and profound prostration; urine suppressed; "when first seen, child was suffering from acute Bright's disease." Antitoxin, 800 units, seventh day. Death on eleventh day.
- 16. Male, seven years (February, 1897). Hoarseness, cough, dyspnœa and stenosis; pulse not very strong; neck glands enlarged; left lung finally involved. Antitoxin, 600 units, ninth day; 1,000, tenth day. Death, tenth day.
- 17. Sex not stated, ten years (March, 1897). Temperature, 99.8°; pulse, 130, weak and intermittent; great prostration; hoarseness, cough, dyspnœa and stenosis. Antitoxin, 1,000 units, fourth day. Death, fourth day.
- 18. Female, five years (March, 1897). Temperature, 101.8°; pulse, 130, extremely weak; membrane covering pharynx and in the nose; neck glands swollen. Antitoxin, second day, 1,000 units. Convulsions and death, third day.
- 19. Sex not stated, one year (March, 1897). Temperature, 104°; pulse, 130, strong; membrane on both tonsils and in the nose. Antitoxin, 1,000 units, third day. "Profuse bleeding from nose, causing death in a short time."
- 20. Female, six years (April, 1897). Pulse, 130; marked prostration; membrane on both tonsils and soft palate; neck glands enlarged; urine nearly suppressed for forty-eight hours before death. Antitoxin, 800 units; time not stated. Death, ninth day.

Hospital Cases.

- 21. Female, eleven months (January, 1897). Pulse, 120; prostration not excessive; membrane in pharynx; neck glands enlarged. Antitoxin, 1,000 units; time not stated. Death, thirty hours after injection.
- 22. Male, nine years (March, 1897). Great prostration; membrane over pharynx and roof of mouth and in the nose; neck glands very much enlarged. Antitoxin, 4,000 units, in divided doses; time not stated. Great improvement after each injection. Death from exhaustion on eighth day.

It is quite plain that a comparison of the fatality of cases treated with antitoxin with the general fatality of cases of diphtheria previous to the introduction of this therapeutic agent, or even with cases not treated with antitoxin, which occurred at the same period with those so treated, does not do justice to the merits of antitoxin, for the reason that such a comparison must be made between two groups or classes of cases which are not strictly comparable, since one con-

tains a larger and the other a smaller percentage of severe cases. That is to say, the general run of cases treated with antitoxin by physicians in private practice, and especially of those sent to hospital, must necessarily be a selected class, in which the percentage of severe cases is greater than it is in the whole number of cases of diphtheria occurring or reported in a given community.

It has been urged, and with some degree of reason, that the diminution in the fatality from diphtheria is partly due to the introduction of bacterial diagnosis by means of cultures from the throat, whereby mild cases of illness are shown to be cases of true diphtheria, which would otherwise have passed unnoticed. But this statement is in some measure offset by the fact that a considerable number of cases which might have passed for diphtheria before the days of bacterial diagnosis are now classed as "negative."

The present report gives support to the belief that the value of this argument has been over-estimated, since the cases in which cultures were made are here separated from those in which they were omitted, and the fatality in each group differs but slightly. This fact does not, however, in the least degree undervalue the importance of having a careful diagnosis made by means of cultures in each case, either before the administration of antitoxin, or as soon as possible after the beginning of treatment.

The most important lesson which is taught by these returns is the necessity of early administration of the antitoxin in each and every case.

Out of 136 cases in which antitoxin was administered on the first day of illness, there were only 2 deaths, or 1.5 per cent., and 1 of these deaths occurred in the case of an adult male who was stated to be a man of excessively intemperate habits and enfeebled by drink.

That this experience is not peculiar to Massachusetts is shown by the accompanying table, in which the effect of delayed administration is very conclusively demonstrated. In almost every collection of statistics of this character the fatality appears to increase with a considerable degree of uniformity from the first day onward.

As is usual in all similar tables of figures, the larger numbers present the more uniform results. From an inspection of this collection of more than 20,000 cases treated with antitoxin, the probability of recovery or of a fatal result in an average case may readily be estimated.

^{*} In this number (989) 43 cases in which a bacterial diagnosis showed negative results are not included, so that the whole number treated with antitoxin of which returns were made to the Board was 1,032.

DIPHTHERIA CULTURES EXAMINED DURING THE YEAR ENDING MARCH 31, 1897.

The following table presents the information obtained from the records of the Board relative to the number of diphtheria cultures examined during the year ending March 31, 1897, together with the names of the cities and towns for which this work was done and the numbers which proved to be positive and negative in each place.

Number of Cultures examined from April 1, 1896, to March 31, 1897.

In addition to the foregoing table another list is presented in which the information relates to those cultures which were examined in order to determine the question of the release of the patient from isolation or quarantine. The length of time during which the bacilli of diphtheria persisted is given in weeks.

Persistence of Diphtheria Bacilli in the Throat from the Date of the Earliest Symptoms (including all Cases where Cultures for Release were made, up to June 13, 1897).

The following circular of information was issued by the Board and sent to local boards of health throughout the State: -

THE DIAGNOSIS OF DIPHTHERIA BY MEANS OF CULTURES.

[A Circular of the State Board of Health of Massachusetts.]

The term "diphtheria" is now by common consent confined to those affections of the throat, nose, larynx and trachea which are associated with the bacillus of diphtheria. Affections resembling diphtheria clinically, but not traceable to diphtheria bacilli, appear to be common. According to extended studies, especially those of Park of New York, the mortality of such affections is quite low. The importance of determining promptly in all throat affections whether the diphtheria bacillus is present or not is threefold.

1. The use of antitoxin is not infrequently based upon the diagnosis, although in all cases which begin with threatening symptoms, and which the physician considers, clinically, as diphtheria, it is far wiser to use the antitoxin at once rather than wait twenty-four hours.

- 2. A more important use of a correct diagnosis is in the application of measures designed to prevent the further spread of diphtheria to the healthy members of the afflicted household and to children in school.
- 3. At the present time it is further desirable to collect accurate statistical evidence of the efficacy of the antitoxic serum, and this evidence is not valuable unless the nature of the cases treated with it is definitely known. This is clear from the fact that antitoxic serum is directed only against affections produced by the bacillus of diphtheria, and, so far as known, it has not the power of neutralizing the products of other poisonous pathogenic bacteria.

The Massachusetts State Board of Health is now prepared to make the diagnosis of diphtheria by means of cultures. The method adopted is that first introduced into New York city by its board of health. A box containing a culture tube and a swab is sent out. The attending physician prepares the culture in accordance with printed directions accompanying every box. After the culture tube has been inoculated from the throat of the patient and the accompanying blank filled out, both are returned without delay by express or messenger to the State Board of Health, Room 141, State House, Boston.

The cultures, under favorable conditions, will be ready for examination on the morning after the receipt of the box, and a message will be sent out as soon as the examination has been completed. A telegram or telephone message will be sent if so desired, but it is expected that all express, telegraph and telephone charges will be at the expense of the local boards of health or physicians from whom the requests for bacteriological examinations are received.

The success of the diagnosis will depend largely upon the care exercised by the physician in making the inoculation. The directions accompanying the tubes should be consistently followed out, and a special effort should be made to bring the swab in contact with any existing exudate. The failure of the culture may be due to a number of causes. The membrane may be low down, beyond the reach of the swab; * antiseptics may have been applied to the throat shortly before the culture was made; the culture medium used may be too old and too dry to favor the growth of the implanted bacteria, or it may have been contaminated with bacteria before use. The dryness of the nutrient serum shows itself by a marked concavity of the surface to be inoculated (a slight concavity being usually present), any foreign growth, by spots on the smooth, whitish surface of the serum. Such tubes should not be used if others are accessible, but returned promptly. The physician inoculating the tube may injure the culture by careless, clumsy handling of the swab, thrusting it into the culture

[•] In cases of membranous croup the diphtheria bacilli are more likely to be found in cultures from the throat later on in the disease, probably because they have been coughed up.

medium and breaking it up instead of gently rubbing it over the surface. The accuracy of the culture diagnosis thus depends largely on the physician inoculating the tube, and it would be to the advantage of all concerned if the suggestions herein contained and the directions accompanying the box were carefully studied before the culture test is made.

The bacteria encountered on the mucous membranes of the throat are of several kinds: (1) micrococci (staphylococci and streptococci), usually regarded as the cause of the mild, non-diphtheritic anginas, and present to a greater or less extent in all throats; (2) bacilli not easily distinguishable from the true diphtheria bacilli and usually denominated pseudo-diphtheria bacilli; and (3) the genuine diphtheria bacilli.

It is not contemplated by this service to furnish a guide for the use of diphtheria antitoxin, because of the delays which may be anticipated in the transmission of the boxes from one portion of the State to another. The object of the culture diagnosis will be to supply the physician or health officer with a more reliable guide than can be furnished by the clinical diagnosis in preventing the spread of the disease through the household and thence into the community. Until information has been received, suspected cases should always be treated as true diphtheria, and the precautions taken which are laid down in another circular of information on this disease relative to isolation and disinfection. The administration of diphtheria antitoxin should not be delayed until the return notice has been received if the case is one which arouses apprehension, since the efficacy of the serum diminishes with the progress of the malady.

The persistence of diphtheria bacilli in the throat of recovered persons has been frequently demonstrated, and it has now become customary in cities to examine the throat after recovery to determine whether or not the infectious agent is still present. If diphtheria bacilli are found, the person is still in a position to disseminate the disease. The period of time following the disappearance of the membrane during which the bacilli are still present varies from case to case. They may be absent on the day following the disappearance of the membrane, or they may be detected for weeks thereafter.

Cultures designed to reveal the presence of diphtheria bacilli after the subsidence of the disease will be examined in special cases if desired by the health authorities immediately concerned. In all cases it is highly desirable to keep children out of school for at least two weeks after recovery, and to warn older convalescents not to kiss children and to guard themselves for several weeks against any act which would favor the direct or indirect transfer of bacteria from their mouths to those of others.

STATE HOUSE, BOSTON, March, 1896.

[Copy of blank form provided with each culture outfit.]

DIPHTHERIA.

No.

City or town,

Name of patient,

Age,

Name of physician,

Address of physician,

Date and hour of culture, Date of earliest symptoms,

Location of exudate,

Any local application shortly before inoculation of culture tube?

Source of infection,

Clinical diagnosis,

(Return both tubes with swab and this schedule filled out.)

RETURN BOX BY EXPRESS ONLY.

All charges of transmission must be paid by the local authorities or by the persons who forward the packages. It will facilitate the work of diagnosis if local boards and physicians will inform the State Board as to the mode of replying, i. e., by mail, telephone or telegraph.

In order to ensure promptness in replying, it is desirable that culture tubes should be left at the office of the Board, Room 141, State House, between 9 A.M. and 4 P.M., and on Saturdays before 1 P.M.

MALARIA.

The prevalence of malaria in certain portions of this State for some years past, its persistence in some of these localities and the endemic character which it is beginning to assume make the possession of more accurate knowledge concerning its genesis and diffusion a thing greatly to be desired.

The hypotheses hitherto held concerning the origin of malaria in temperate climates, such as proximity to stagnant waters and the upturning of the soil, undoubtedly are conditions necessary to its genesis, but there are other unknown factors which only future observation and study can bring to light. Until these are known, and thereby the chain of events which mark the various steps in the life history of the malarial parasite completed, we are exposed to the danger of misinterpreting the significance of the conditions now known and giving them either too great or too little value in combating the disease.

The necessity for more information is thus evident. To obtain this from different parts of the State, the interest of physicians must be aroused and their service enlisted. Only the practising physician is likely to become cognizant of cases of this ephemeral and sporadic disease. He, also, is likely to overlook it because of its apparently slight importance or to confound other ailments with it. Not infrequently it is dealt with in silence on account of the fear that a knowledge of its prevalence would injure the attractiveness and prosperity of the infected locality. It is not improbable that a complete knowledge of the genesis of malaria will, by showing all the factors involved, relieve just such localities or communities of the odium involved, because it must show a way out of the difficulty. Co-operation in such investigation is therefore the duty of precisely such localities as are most afflicted, because the facts there obtainable are best adapted to a successful study of the causation.

In order to accomplish the object of gathering information and at the same time assisting the physicians and removing the facts collected from the domain of guesswork, the microscopic diagnosis of malaria by an examination of the blood was made a part of the regular work of the laboratory. In order to bring this work to the notice of physicians and to instruct them in the method of preparing the blood films the following circular was distributed:—

OFFICE OF STATE BOARD OF HEALTH.

THE DIAGNOSIS OF MALARIA.

The evident encroachment of malarial diseases upon new territory and the intensification of the infection in certain localities make it of importance to search more thoroughly than has been done heretofore for the primary factors concerned in the dissemination of these diseases.

To accomplish this purpose in part an accurate knowledge of the distribution of malaria is necessary. This requires the elimination of diseases or conditions often called malarial which are due to other causes, and, on the other hand, the recognition of cases of malaria now and then overlooked when the symptoms are not sufficiently typical.

In pursuing the investigation of malaria the State Board of Health proposes to make diagnoses of this disease whenever called upon to do so. Since it has been definitely shown that the different types of malarial fever are always associated with certain minute organisms within the red corpuscles of the blood, the method of diagnosis is restricted to the microscopic examination of this fluid. The following procedure will be used:—

Cover-glasses, in small boxes, will be mailed on application to all those who may expect to meet malaria during the warm season. These are to be used in collecting a small amount of blood from the suspected case and forwarding it to Room 141, State House, Boston.

The blood films are prepared in the following manner: -

The tip of a finger or the lobe of one ear is thoroughly cleansed with soap and water and dried carefully. If desired, the part may also be washed with alcohol and ether to remove any remaining scales or oily matter. An ordinary surgeon's needle, previously passed through the flame of an alcohol lamp or a gas burner or held over the chimney of a kerosene lamp for a few seconds to sterilize it, is used to prick the part until a small drop of blood exudes. This may be wiped away with a clean cloth and the second drop used. This is touched with the edge of a cover-glass and the edge carrying the drop placed on a second cover at an angle of 20 to 30 degrees and drawn across its entire face. A thin film of blood will be deposited on the second cover which dries rapidly. Three or four such films should be

prepared if possible, each one from a freshly exuding drop, and laid down to dry. A slight manipulation of the part pricked will cause the blood to continue to ooze from the same puncture until the necessary preparations have been made. The points to be borne in mind in this operation are great cleanliness, rapidity of work and the use of a fresh drop of blood, as the corpuscles shrivel soon after exposure to the air. Everything should be put in readiness and within reach before the skin is pricked, to avoid delay in making the films.

The film should be very thin so that the corpuscles may be fixed almost instantly on the glass by drying. The thinner the film, other things being equal, the more perfect the preservation of the corpuscles. A thin film cannot be obtained from a large drop of blood, hence the operator should not wait until the exuding drop becomes too unwieldy. It is better to wipe away a large drop and work with the following smaller one. When the cover-glasses are thoroughly dry—and this should not require more than fifteen to thirty seconds—they are wrapped separately in the paper provided and replaced in the box. This should be filled with the paper so that the glasses cannot move about.*

Slides may be used in place of cover-glasses by those preferring them. The manipulation is the same as with cover-glasses. The edge of one, charged with the drop of blood, is drawn rapidly but steadily over the face of the other at an angle of 20 to 30 degrees. The slides must be scrupulously clean. Drawing them rapidly through a flame often destroys the film of grease when other means have failed to remove it. The edges of the slide which receives and distributes the blood should be ground, or, at any rate, very even, otherwise the film will be imperfect.

The best time for taking the blood is during a chill, or, in doubtful cases, when the suspicious symptoms are most pronounced. Since quinine has a destructive effect upon malarial parasites, films prepared after the administration of this drug may not contain these organisms in numbers sufficient to be detected and the microscopic diagnosis may be misleading.

The accompanying blank should in all cases be filled out and returned with the preparations of blood.

STATE HOUSE, BOSTON, May, 1896.

The blank which is to be filled out contained the following queries:—

^{*} Physicians are cautioned against laying covers together with the drop of blood between them and sending them in this condition. Nor should they be placed together, face to face, and then drawn apart, as for some kinds of bacteriological work.

MALARIA.

1. No.

2. Locality,

3. Name of patient, Age,

4. Name of physician,

5. Address of physician,

6. Symptoms of the case,

7. Probable source of infection if any suspected,8. Date of season of last former attack, if any,

9. Date of preparations and relation in time to chill, if any,

10. Any quinine or other medicine administered before preparation of films, Remarks:

Of these questions Nos. 8 and 9 deserve a passing notice. In tracing the distribution of malaria it is evidently necessary to distinguish between patients who have never before been affected and those who have had attacks before. Since the malarial parasite very probably lives in the blood for a variable or indefinite period of time after the symptoms of an attack have passed by, the renewed outbreak of the disease must not be interpreted necessarily as a fresh infection although it may be. The past history of the patient should therefore be carefully noted. Since the blood parasite varies in size and appearance at different intervals after the chill or paroxysm, the microscopist should know how many hours after the last or before the expected chill the blood films have been prepared, so as to be guided by this information during the examination.

In response to this circular preparations from 57 patients have been sent in for examination between April 1, 1896, and April 1, 1897. The experience gained in looking over these preparations, as well as those sent in before and after the year as limited above, has revealed certain difficulties of a minor character. In the first place, the microscopist is limited to the blood films taken at some one moment and is unable to repeat the examination if desirable, as is the case in hospitals and private practice. If the preparations have been hastily made or without following carefully the directions given the blood films are frequently of little or no use. Again, the physician, being called usually during a chill, is not likely to reach the patient until this has subsided. The blood films sent are thus usually made soon after a chill, when the recognizable parasites are fewest and smallest in the whole cycle between consecutive chills. But this is not a serious obstacle and the diagnosis can, as a rule, be made.

The result of the examination of the preparations is best shown in the following table:—

| | | | | Number of Patients. | Positive. | Negative. |
|---------------|--|--|------|---------------------|-----------|-----------|
| Ayer, | | | | $\frac{1}{2}$ | 1 | 1 |
| TO Touris | | | | 1 | 1 | _ |
| East Douglas, | | | | 3 | - | 3 |
| Everett, . | | | | 1 | _ | 1 |
| Hyde Park, | | | | 5 | - | 5 |
| Leicester; . | | | | 1 | _ | 1 |
| Northbridge, | | | | 1 | 1 | _ |
| Norwood, . | | | | 1 | _ | 1 |
| Uxbridge, . | | | | 41 | 24 | 17 |
| Waltham, . | | | | 1 | 1 | - |

Of preparations from 57 patients those from 28 contained malarial organisms. Lest this low percentage of positive cases might be used as a witness against the efficiency of the method it should be stated that among these cases are

- 1. Several who were affected with some other malady but upon which the physician hoped to get light from the examination of the blood.
- 2. A number of cases in which the physician himself failed to make a positive diagnosis from the clinical side.
- 3. A considerable number in which quinine had been given before the preparation of the films.
 - 4. One old case without symptoms.
 - 5. Five cases examined in midwinter.
- 6. A certain number from which imperfect films were received. These though somewhat doubtful were classed as negative.

A further analysis of these cases will not be attempted at the present time but left until more material has accumulated. Such analysis, however, would show that in from 5 to 10 per cent. of all the cases examined the diagnosis was of great value to the physician in charge in clearing up at once the obscure character of the malady.

EXAMINATIONS

OF

SPUTUM AND OTHER MATERIAL SUSPECTED OF CONTAINING THE BACILLI OF TUBERCULOSIS.

[705]

EXAMINATIONS OF SPUTUM AND OTHER MATERIAL SUSPECTED OF CONTAINING THE BACILLI OF TUBERCULOSIS.

The following table presents the results of examination of sputum and other material forwarded to the Board from different cities and towns for the purpose of determining the presence or absence of the bacilli of tuberculosis.

The whole number of specimens examined was 124 and the results were as follows:—

Tabular Statement of Examinations made by the Board for determining the Presence or Absence of the Bacilli of Tuberculosis in Sputum or Other Material presented for Such Examination.

A circular was issued to local boards of health containing the necessary information upon this point, of which the following is a copy: -

No. 34.7

Office of State Board of Health, November, 1896.

THE EXAMINATION OF SPUTUM FOR TUBERCLE BACILLI.

The microscopic examination of sputum for tubercle bacilli will be made by the State Board of Health for those desiring it. A small quantity, preferably not more than one-half ounce, should be sent in a small, widemouthed bottle, suitably protected against breakage, by express or messenger to Room 141, State House, Boston.

Small glass receptacles, properly packed, will be sent on application.

To ensure material for a satisfactory diagnosis, the patient should be requested to reserve only that sputum which is coughed up from the air tubes and lungs and to reject secretions from pharynx and throat. To do this the throat should be thoroughly cleared first, and only the masses subsequently expectorated reserved.

Since tubercle bacilli are quite resistant, and demonstrable in sputum for some time after it has been expectorated, any great haste in sending it is not called for. It should, however, be sent as promptly as possible, especially in warm weather.

The object of the examination of sputum is not so much to enable the physician to make an early diagnosis as to protect the public from manifestly infectious sputum. The Board does not hold itself responsible, therefore, for the occasional non-discovery of tubercle bacilli when they are present in very small numbers.

The repeated and varied examination of sputum found free from bacilli after the usual methods of staining have been carefully applied will not be undertaken excepting under certain not at present definable conditions.

Examination of sputum for special morphological constituents, for pneumonia and influenza germs, is also beyond the scope of this work, and will only be undertaken when the public health warrants it.

The following blank form should be filled and returned with each specimen forwarded to the office of the Board: -

Tuberculosis.

- 1. No.
- 2. Name of patient,

Age,

- 3. Address.
- 4. Occupation,
- 5. Name and address of attending physician or of sender,
- 6. Sputum, when discharged,
- 7. Clinical diagnosis,
- 8. Duration of disease,
- 9. Any other cases in the same household?
- 10. Remarks:

THE

VITAL STATISTICS OF MASSACHUSETTS, 1856-95.

[711]

Note.—The birth, death and marriage rates are indicated by the first, second and fourth irregular lines in the diagram, and represent the ratio per thousand of the living population, the scale being at the left side of the diagram. The infantile death-rate is shown by the third irregular line, and represents the ratio of the deaths under one to the living births per thousand; the scale for this line is at the right side of the diagram.

THE VITAL STATISTICS OF MASSACHUSETTS.

A FORTY YEARS' SUMMARY.

By Samuel W. Abbott, M.D., Secretary of the Board.

The occurrence of a census year affords an opportunity for the presentation of the vital statistics of a community with more than usual accuracy. Each census year forms a milestone or point of departure in the life history of the State, and the data collected in such a year may be used as standards of reference from which, with proper limitations, conclusions may be formed with a degree of certainty which cannot be applied to the statistics of intervening years.

In the present summary of the marriages, births and deaths which occurred in the forty-year period, 1856-95, the methods employed are similar to those which were adopted in the brief summaries of the statistics of 1893 and 1894,* but with greater fulness of detail, especially in those particulars which are of the greatest interest and value to physicians and health officials.

Dr. Longstaff, in commenting on the value of vital statistics, says: "The numerous and very voluminous reports on the very dusty shelves of the library of the Statistical Department of the General Register Office form a vast reservoir, into which a ceaseless stream of facts has been flowing for more than half a century."

The usefulness of these myriads of facts, which likewise in Massachusetts have been accumulating for more than half a century, depends largely upon the carefulness and the clearness with which the compiler treats them, and upon the judicious selection which he makes of the material in his possession.

First in order in the present summary the subject of population is presented, since upon the number and distribution of the population by sexes, ages, races and density depends very largely the value of the observations which are made. Absolute numbers have a definite

^{*} Published in the twenty-sixth and twenty-seventh annual reports of the Board.

value, but this value is very much enhanced when relative numbers are also given, such, for example, as the ratio obtained by comparing the deaths from any disease at any age of life with the numbers of the living at the same age.

The order in which the statistics are presented (marriages, births and deaths) has been adopted in conformity with the general usage of nearly all countries having systems of registration, and because it represents the order of events in each family, natural as well as sociological.

In earlier periods of New England history the county was considered as an important factor, but at the present time the county, statistically considered, is of much less importance, while the city and the urban population are yearly assuming greater interest as the relative numbers of the urban population increase. In 1842, the first year of registration, the population of towns in the State having 10,000 inhabitants in each, constituted only 24 per cent. of the population. In 1895 the population of this class had increased to 69 per cent. of the whole. Hence county statistics will be but little used in this summary.

Of the Accuracy of the Material collected for Publication in the Massachusetts Registration Reports.— The period of forty years (1856-95) has been selected for consideration for the reason that it presents a definite portion of time in which the returns of vital statistics of the cities and towns may be deemed to be fairly accurate. The returns of the first few years following 1842 are more or less incomplete and untrustworthy, but those of the forty years under consideration must be considered as approximately correct.

With reference to a very important portion of the returns, that which relates to the causes of death, the following comments of Dr. Longstaff upon the registration reports of England are so fully applicable to our own statistics that we take the liberty to quote them nearly verbatim:—

I have been more and more convinced of the value of the figures, and fully believe that they may be taken as, on the whole, a fair approximation of the truth. At the same time it is hardly necessary to say that, like all other statistics, they require care and knowledge in handling. Without doubt the figures relating to alcoholism, venereal diseases and perhaps insanity are almost valueless; but that does not prove that those relating to scarlet-fever, pneumonia or cancer are equally valueless. Neither does the fact that a large number of certificates are carelessly filled invalidate

the far larger number that are more trustworthy; indeed, those very sources of error are subject to laws, and are more or less constant factors of the whole. When it is possible, as I have elsewhere proved it to be, to find general laws regulating many of the causes of death, and especially mutual relations between these causes, and relations between some of them and various external phenomena, the only possible inference that I can deduce is that the figures dealt with are the expression, more or less accurate, of facts in nature. . . .

But in spite of what I have just stated, it must be admitted that there are numerous fallacies to which the classification of deaths according to their alleged causes is liable. They are:—

- 1. In a number of cases no cause of death is specified at all.
- 2. (And this is a much more important source of error.) In a large number of cases the cause is stated in such a vague or indefinite manner as to be almost valueless. The terms "atrophy," "debility," "old age," "hemorrhage," "dropsy," etc., give but little information, but it is satisfactory to note that from the beginning of the reports to the last issued the improvement in this respect is steady and continuous. For example, very few cases are now returned simply as "dropsy," but the dropsy is referred to disease of the heart, kidneys, liver or ovaries.*
- 3. Where the cause is definitely assigned, there is good reason to believe that, in a large number of cases, owing to carelessness, ignorance or desire to spare the feelings of relatives, or even less worthy motives, the causes of death assigned are barely approximately correct. The returns themselves indicate that this source of error is also diminishing.

To the foregoing should also be added the fact, stated somewhat differently by Dr. Longstaff, that medicine is a progressive science, and that the frequent discoveries in relation to the natural history of diseases necessitate changes in the terms employed to designate them. New terms are introduced in every decade, and the nomenclature and classification of one half century are replaced by an entirely new system in the next half century.

The sum of the individual records treated in this summary for the forty years, 1856-95, is as follows:—

| Marriages, | | | | • | | | | 630,680 |
|---------------|--|---|---|---|--|---|--|-----------|
| Births, | | | | | | | | 1,780,872 |
| Deaths, | | | | | | | | 1,317,453 |
| Still births, | | • | • | ٠ | | • | | 56,005 |
| Total, | | | | | | | | 3,785,010 |

^{*} The deaths ceitified in Massachusetts as from dropsy in 1856 were 487. Those in 1895 were 88.

POPULATION.

Population constitutes the natural basis of vital statistics and hence should first be considered in the treatment of the subject.

Growth of the Population.

There are two factors which affect the movement of the population, either in an increasing or a diminishing ratio. First, the difference between the births and deaths, and second, the difference between the number of immigrants and the number of emigrants.

The growth of population, consisting in the excess of the births over the deaths is usually termed the natural increase, while that which consists in the excess of immigrants over emigrants cannot be properly termed an increase, but is merely a transfer from one country or community to another.

The first ship's company of a few score persons who landed at Plymouth in 1620, notwithstanding an enormous death-rate in the first few years, had increased in one hundred and forty-five years to 239,764, according to the first colonial census of 1765, but this increase was made up for the most part of new arrivals from beyond the sea, and not from the excess of births over deaths.

During the forty years comprised in the present report (1856-95) the population of the State more than doubled, the increase from the census of 1855 to that of 1895 amounting to 1,367,814, but of this number, 904,395, or nearly two-thirds, consisted of immigrants from other States and countries, since the excess of births over deaths during these forty years amounted to only 463,419. The growth of population, therefore, in the past forty years may be said to consist of the excess of births over deaths, and the migration, in the ratio of about one of the former to two of the latter.

In the following table (1) are presented the enumerated populations in each of the years in which a census was taken (either colonial, State or national). The annual rates of increase at each intercensal period varied from a minimum of .58 of 1 per cent. annually in the period of civil war, to a maximum of 3.03 per cent. in the period 1840-50.

Sex. — In the next table (2) is presented the population at each census by sexes, together with the percentage of each sex, and the ratio of females to 1,000 males, by which it is shown that the females have invariably been in excess at each census enumeration, the least

difference occurring at the census of 1840, when the females were in the ratio of 1,019 to 1,000 males, and the greatest difference being in 1865, when the females were in the ratio of 1,105 to 1,000 males. This census was taken just at the close of the war, but while a considerable portion of the troops had not yet returned home.

If the growth of population in Massachusetts be reckoned by centuries, it may be said to have increased in the seventeenth century, in the eighty years, 1620 to 1700, from 0 to about 100,000 in round numbers, in the eighteenth from 100,000 to 422,845 (one hundred years), and in the nineteenth from 422,845 to 2,500,183 (ninety-five years).

The descendants of the Indians of Massachusetts are now less than 800 in number, and are mostly, if not all, of mixed blood.

Note. — The figures for each of the census enumerations prior to but not including 1820 present the numbers of the sexes for white persons only, the sex of colored persons being omitted in the published returns. In the returns for 1765 there appears to have been a considerable number, in addition to the colored population, who were not classified by sex. The total population at the census of 1765 does not include 1,569 non-taxable Indians, and that of 1776 does not include 4,761 colored persons.

Ages. — In Table 3 are presented the numbers of the population at different age periods for each of the census years from 1855 to 1895, together with the percentages of the total population. These figures show that the relative numbers of the population at ages under 20 have diminished during these forty years, those of the age period 20–30 have remained nearly stationary, while those of the later ages have increased.

The deficiencies of the census at ages under five years have received sufficient comment in the twenty-sixth annual report of the Board, pages liii-lvii.

Population by Nativity and by Races.

Under the term "nativity" it has been the custom in most statistical documents to group the component parts of the population into two classes, one of which comprises the population born in the United States and the other embraces the sum of the persons of different nationalities born outside the United States. The term, however, so far as statistics are concerned, must be regarded very largely as one of degree, since nearly the entire population is descended from foreign ancestry of greater or less remoteness of degree. No census enumeration has attempted to gather information dating back more than two generations at the farthest.

The following table presents the numbers and percentages of the native and foreign populations at different census periods:—

| YEAR. | | | | | |
|-----------|-------|-----------|----------|---------|----------|
| | | Native. | Foreign. | Native. | Foreign. |
| | | 830,490 | 164,024 | 83.51 | 16.49 |
| | | 886,575 | 245,263 | 78.33 | 21.67 |
| | | 970,960 | 260,106 | 78.88 | 21.12 |
| | | 999,976 | 265,486 | 79.02 | 20.98 |
| | | 1,104,032 | 353,319 | 75.76 | 24.24 |
| | | 1,225,829 | 418,904 | 74.53 | 25.47 |
| | | 1,339,594 | 443,491 | 75.13 | 24.87 |
| | | 1,415,274 | 526,867 | 72.88 | 27.12 |
| | | 1,581,806 | 657,137 | 70.65 | 29.35 |
| | | 1,735,253 | 764,930 | 69.41 | 30.59 |
| • | : : : | | | | |

Table 4.— Population by Nativity in Census Years (Massachusetts).

Note. — In each of the census enumerations of 1855, 1865 and 1875 a small number of persons whose nativity was unknown (in no case more than 1 per cent.) is excluded from the table.

From the foregoing table it appears that the foreign population has increased from a percentage of 16.49 in 1850, to 30.59 in 1895, the greatest relative increase having taken place between 1850 and 1855.

Race. — The following table presents the population classified as white and colored, the latter term embracing negroes, mulattoes, Chinese, Japanese and Indians: —

| | | | | POPULS | ATION. | PERCEN | TAGES. |
|-------|------|----|--|-----------|----------|--------|----------|
| | YEAR | S. | | White. | Colored. | White. | Colored. |
| 1850, | | | | 985,450 | 9,064 | 99.09 | .91 |
| 1855, | | | | 1,122,463 | 9,906 | 99.13 | .87 |
| 1860, | | | | 1,221,432 | 9,602 | 99.22 | .78 |
| 1865, | | | | 1,256,864 | 10,167 | 99.20 | .80 |
| 1870, | | | | 1,443,156 | 13,947 | 99.04 | .96 |
| 1875, | | | | 1.635.620 | 16,292 | 99.02 | .98 |
| 1880, | | | | 1,763,782 | 18,697 | 98.95 | 1.05 |
| 1885. | | | | 1,922,944 | 19,197 | 99.01 | .99 |
| 1890, | | | | 2,215,373 | 22,144 | 99.01 | .99 |
| 1895. | | | | 2,471,418 | 28,765 | 98.85 | 1.15 |

Table 5. — Population, White and Colored (Massachusetts).

In the following table are presented the vital statistics of the State for the whole period of registration, including the estimated population for intercensal years and the rates per 1,000 living:—

Table 6.— Marriages, Births and Deaths in Massachusetts (1842-95), with Population and Rates per 1,000 Living.

All estimates of intercensal years are made in accordance with the rule recommended by Dr. Farr (the geometric rate of increase).

The vital statistics of the first seven years of registration (1842-48), together with the returns or marriages for 1849, must be regarded as extremely defective; many of the returns from Suffolk County for this period are wanting, together with those of some of the small towns. From the year 1849 onward the omissions probably constitute but a small percentage only of the total registration.

The figures for the population of census years are given in bold type.

INTERSTATE AND INTERNATIONAL VITAL STATISTICS.

The following table presents the marriage, birth and death rates of the New England States and the principal civilized countries of the world for 1893, 1894 and 1895:—

TABLE 7. - Summary of the Fital Statistics of Principal Countries for 1893, 1894 and 1895, together with those of the New England States.

MARRIAGES.

The whole number of marriages registered in Massachusetts in 1895 was 23,102, and the marriage-rate per 1,600 of the living population was 9.24. The number of persons married in each 1,000 of the population was 18.48, as compared with a rate of 16.86 in 1894 and 19.07 in 1893. Comparing the two twenty-year periods 1856-75 and 1876-95, the marriage-rates were 19.77 for the former period and 17.94 for the latter, so that there has been a decrease of 1.83 per 1,000, comparing the two periods.

The successive five-year periods show considerable fluctuations and are as follows, beginning with the period 1856-60: 19.62, 18.66, 20.96, 19.73, 15.66, 18.54, 18.62 and 18.50.

The following table presents the number of marriages with the marriage-rates for each year, each five-year, ten-year and each twenty-year period. The numbers for earlier years may be found in the table on page 721.

Table 8. — Marriages and Marriage-rates, Massachusetts, 1856-95.

| | | MAR | RRJAGE-R | ATES. | | | MAR | RIAGE-RA | TES. |

| 1866, | 14,428 14,451 13,856 14,826 14,721 15,746 16,142 16,437 15,564 13,663 | 22.14 21.57 20.12 20.92 20.20 21.08 21.08 20.92 19.32 16.54 | }20.96 }19.73 | 20.31 | 1886, | 18,018 19,533 19,739 20,397 20,838 21,675 22,507 22,814 20,619 23,102 | 18.04 19.00 18.66 18.74 18.62 18.94 19.07 16.86 18.48 | 18.62 | 18.56 |

Mean of forty years = 18.67.

The maximum marriage-rate in any year of the forty-year period was 22.14 per 1,000 in 1866, and the minimum was 14.91 in 1878.

The marriage-rate of England has declined slightly, from a maximum of 17.9 in 1853 to a minimum of 14.2 in 1886, and then slightly increased to 15.6 in 1891. Those of Denmark, Sweden and Hungary have declined slightly, while those of Prussia, Italy and France have remained nearly stationary.

A more correct measure of the marriage-rate is the relation of the number of marriages to the number of unmarried persons of marriageable age of each sex. For this purpose the figures of the State Census of 1885 are selected, and it is assumed that males are marriageable at the age of sixteen and females at the age of fifteen. A very small number of females were married at ages under fifteen, but the number was less than one-tenth of one per cent. of the total number of females who were married in that year. The term "marriageable population" embraces all single persons, divorced, and widowers and widows of the ages named.

The following figures present the ratio of the married persons to the marriageable persons of the same year:—

Table 9.— Relation of Marriages to Marriageable Population in Massachusetts, 1885.

| Marriageae | BLE PERSONS. | Persons Married of | | OF MARRIAGEABLE |
|------------|--------------|--------------------|--------|-----------------|
| Males. | Females. | Each Sex. | Males. | Females. |
| 277,180 | 370,973 | 17,052 | 61.5 | 46.0 |

Marriages to Each 1,000 Marriageable Persons of Each Sex in Different Countries.

| Countrie | s. | | Males. | Females. | Countries. | Males. | Females. |
|--|----|---|----------------------------|----------------------------|------------------|------------------------|----------------------|
| Bavaria, Würtemberg, . Austria, Italy, France, | | • | 57 64 58 49 57 | 44 45 50 49 46 | England, Sweden, | 62 53 50 61.5 | 53 37 39 46 |

The foregoing figures comprise the statistics of about eight million marriages in the countries named, and require the following interpretation: The term "marriageable persons" in the figures for Austria, Italy and England relates to such unmarried persons of each sex as are fifteen years of age and over. In the figures for Switzerland it relates to men eighteen years old and over and women sixteen years old and over.

Ages. — The following table presents the average age at marriage of all men and women married, and of all men and women married for the first time, for the five years 1891-95:—

Table 10.— Mean Age at Marriage, 1891-95, in Massachusetts, expressed in Years and Fractions of a Year.*

| | | YEAR | is. | | | Average Age of All Bridegrooms. | Average Age of All Brides. | | Average Age of Women Marrying the First Time. |
|-------|--|------|-----|---|-----|---------------------------------------|-------------------------------|-------|---|
| 1891, | | | | | | 28.85 | 25.53 | 26.82 | 24.28 |
| 1892, | | | | | .] | 28.85 | 25.37 | 26.76 | 24.24 |
| 1893, | | | | | | 28.90 | 25.47 | 26.86 | 24.40 |
| 1894, | | | | ٠ | | 29.10 | 25.59 | 26.93 | 24.39 |
| 1895, | | | | | | 28.91 | 25.59 | 26.89 | 24.42 |

^{*} For earlier years see forty-ninth registration report, 1890.

The figures for England differ but little from those of Massachusetts, and show a tendency toward increasing age at marriage for both sexes.

Table 11. — Mean Age at Marriage, in England, 1885-95.

| | | YEA | RS. | | All Men. | All Women. | Bachelors. | Spinsters. |
|-------|--|-----|-----|--|----------|------------|------------|------------|
| 1885, | | | | | 28.15 | 25.86 | 26.08 | 24.58 |
| 1890, | | | | | 28.32 | 26.03 | 26.38 | 24.81 |
| 895, | | | | | 28.42 | 26.16 | 26.59 | 25.04 |

For the two twenty-year periods, 1856-75 and 1876-95, the mean ages of males and females at marriage were as follows:—

Table 12.— Mean Age at Marriage, Massachusetts, 1856-95.

Men.

| TWEN | ГҮ-ҮЕ. | AR PER | HODS. | | Whole Number of Persons whose Ages were known at Time of Marriage, | Total Years of Life lived at Date of Marriage. | Mean Age at Marriage in Years and Fractions of a Year. |
|----------------------|--------|--------|-------|---|---|--|--|
| 1856-75, 1876-95, | | : | | | 261,882 363,723 | 7,640,653 10,548,543 | 28.85 29.00 |
| | | | | | Women. | | |
| 1856-75, 1876-95, | : | : | : | : | 264,258 363,553 | 6,585,332 9,236,727 | 24.92 25.41 |

By the foregoing table it appears that the mean age of men at marriage has increased from 28.85 to 29 years, or fifteen hundredths of a year, or about one month and twenty-five days, comparing the first period of twenty years with the latter period. The mean age of women has increased during the same time forty-nine hundredths of a year, or about five months and twenty-eight days.

Nativity. — The nativity of persons married in Massachusetts during 1895 was as follows, in percentages of the total number married whose nativity was known: Native born, 55.63; foreign born, 44.37.

Three couples whose nativity was unknown are not included in the foregoing figures.

For the whole period of forty years, divided into two twenty-year periods, the statistics were as follows:—

| Period. | Couples. | American. | Foreign. | American Male. | Foreign Maie. | Unknown. | PERCES American | |
|------------|----------|-----------|----------|-------------------|------------------|----------|-----------------|-------|
| 1856-75, . | 266,667 | 152,435 | 79,840 | 14,397 | 17,256 | 2,709 | 63.75 | 36.25 |
| 1876-05, . | 364,013 | 185,922 | 104,447 | 38,956 | 34,537 | 151 | 61.20 | 38.80 |

Table 13. — Marriages by Nativity for the State, 1856-95.

From the foregoing table it appears that the whole number of native-born persons married in the first twenty-year period was 336,553, or 63.75 per cent., and those of foreign birth were 191,263, or 36.25 per cent.

In the second period the persons of native birth were 445,337, or 61.20 per cent., and those of foreign birth were 38.80 per cent. In this table those of unknown birth are excluded in calculating the percentages.

The foregoing figures convey no information as to the marriagerates of persons of native and of foreign birth. This information can only be gained by a comparison of these groups of the population with the marriages or persons married in each.

The following table presents the population at census years, with the number of persons married and the marriage-rates of each group:—

Table 14. — Marriages and Marriage-rates by Nativity, Massachusetts (1850-95).

| | | Popul | ATION. | Persons | MARRIED. | MARRIAGE-RATES. | | |
|-------|-------|-----------|----------|---------|----------|-----------------|----------|--|
| | YEAR. | Native. | Foreign. | Native. | Foreign. | Native. | Foreign. | |
| 1850, | | 830,490 | 164,024 | 13,486 | 5,798 | 16.24 | 35.35 | |
| 1855, | | 886,575 | 245,263 | 14,790 | 9,492 | 16.68 | 38.70 | |
| 1860, | | 970,960 | 260,106 | 15,363 | 8,911 | 15.82 | 34.26 | |
| 1865, | | 999,976 | 265,486 | 16,942 | 9,036 | 16.94 | 34.04 | |
| 1870, | | 1,104,032 | 353,319 | 18,795 | 10,617 | 17.02 | 30.05 | |
| 1875, | | 1,225,829 | 418,904 | 17,752 | 9,572 | 14.48 | 22.85 | |
| 1880, | | 1,339,594 | 443,491 | 21,499 | 9,571 | 16.05 | 21.58 | |
| 1885, | | 1,415,274 | 526,867 | 21,593 | 12,499 | 15.26 | 23.72 | |
| 1890, | | 1,581,806 | 657,137 | 23,866 | 17,780 | 15.09 | 27.06 | |
| 1895, | | 1,735,253 | 764,930 | 25,701 | 20,497 | 14.81 | 26.80 | |

From the foregoing table it would appear at first sight that the marriage-rate of the foreign population is very much in excess of that of the native population, the excess ranging in different census years from 34 to 132 per cent.

There are, however, certain reasons for this excessive difference which exists in the age constitution of these two groups of the population. In the native population the age distribution approaches quite nearly that of a normally constituted population, like that of Sweden, while that of the foreign population is influenced by the age of the immigrants entering the State. Of the immigrants who entered the United States at several successive census periods, more than one-half were between the ages of fifteen and thirty years and more than two-thirds were between the ages of fifteen and forty. note, page iv, twenty-sixth report of State Board of Health, 1894.) Furthermore, while the population of foreign birth constituted 27.1 per cent. of the total population by the census of 1885, the foreign population under fifteen years of age was only 7.3 per cent. of the total population of those ages, and the foreign population between the ages of fifteen and sixty constituted 34.6 per cent. of the total population of those ages, as shown by the following table: -

Table 15.— Percentage of Native and Foreign Population at Certain Ages, 1885, in Massachusetts.

| Age | Peri | ODS. | | ĺ | Native. | Foreign. | |
|--------------------------|------|------|--|---|---------|----------|-------|
| All under fifteen years, | | | | | 92.7 | 7.3 | 100.0 |
| Fifteen to sixty years, | | | | | 65.4 | 34.6 | 100.0 |
| All over sixty, . | | | | | 70.6 | 29.4 | 100.0 |

Since the period fifteen to sixty embraces nine-tenths of all persons of marriageable ages, it follows that, other things being equal, the class having relatively the greatest number of persons at these ages would show the greater marriage-rate. This, however, can account for only a fraction of the excess.

Races. — The only registration reports of Massachusetts in which the vital statistics of different races are given are those of 1888 and 1889.

The following table presents the number of persons married and marriage-rates of those years, both of the white and of the colored population:—

Table 16. — Persons Married, 1888 and 1889, White and Colored, and Marriagerates.

| | | | ESTIMATED 1 | POPULATION. | Persons | MARRIED. | | RATES (PER- |
|-------|-------|----|-------------|-------------|---------|----------|--------|-------------|
| | YEARS | 3. | White. | Colored. | White. | Colored. | White. | Colored. |
| 1888, | | | 2,094,220 | 20,916 | 38,969 | 509 | 18.4 | 24.4 |
| 1889, | | ٠ | 2,154,637 | 21,522 | 40,309 | 485 | 18.7 | 22.5 |

In the foregoing statement the term "colored" embraces negroes, mulattoes, Chinese, Japanese and Indians. The Chinese, Japanese and Indians have at no time within the forty-year period under consideration constituted more than 5 per cent. of those enumerated as colored persons.

Marriages by Months. — For the two twenty-year periods, 1856-75 and 1876-95, the figures were as follows:—

Table 17. — Marriages by Months, 1856-95, with Relative Figures for Other Countries.

| | | | | | | MARR | IAGES. | MONTHL | Y RATIO RI | DUCE | O TO A | STA | NDARD | OF 10 | 00. |

^{*} In each of the eight columns of relative figures the inaccuracies due to the unequal length of the months are eliminated. The figures in the last six columns are the result of observations upon over five million marriages in the countries named.

From the foregoing table it appears that during the forty years 1856-95 considerable changes have taken place in the times and seasons selected for marriage, when the two twenty-year periods are compared. Using the number 100 as a standard of comparison in each instance, there appears to have been a decrease in January in the intensity of the marriage-rate, from 8.7 per cent. above the mean to 3 per cent. below it. In April, there was an increase from 2.2 below the mean to 1.8 per cent. above it. In May, there was a decrease from 2.7 above to 10.5 per cent. below the mean.

The greatest divergence from the mean appears in March and November, that of March having increased from 37.5 below the mean to 45.1 per cent. below, and that of November having decreased from 51.6 above the mean to 47.8 above. Religious and social customs undoubtedly account largely for these differences in the marriage-rate in different months as well as for the differences between the conditions prevailing in the two twenty-year periods.

The months of June and October have increased considerably in popular favor as months for marriage, as also appears by consulting the following figures for the single year 1895.

For the single year 1895 the monthly ratios (upon a standard of 100) were as follows: First six months in their order, 87.4, 96.4, 43.8, 97.5, 74.4, 151.5; second six months, 84.0, 80.6, 120.7, 141.2, 144.7, 81.0.

The mean daily number for the year was 63.3.

The mean daily number of marriages had increased from 36.4 per day in the first twenty-year period to 49.8 in the second, while the mean daily numbers in the extreme years 1856 and 1895 were 33.5 and 63.3.

FECUNDITY OF MARRIAGE.

The marriages in any year give rise to births which are recorded during the following twenty years or nearly so. The division of the sum of these births by the marriages would express the fecundity of the marriages, but it is impossible to follow each family and count the children, hence some ready method must be adopted for estimating the fecundity. In a stationary population in which the marriages do not increase from year to year, the births of any year might be divided by the marriages of the same year to obtain the desired result, but the marriages are constantly increasing, hence the births of a given year must be divided by the marriages of a previous year. Since the ages of mothers are not a matter of record, the interval in Massachusetts which intervenes between the mean age of marriage and the mean age of mothers when their children are born is unknown.

This interval in Sweden is six years, and Dr. Farr assumes a similar period for England. In the twenty-eighth registration report of Michigan (1894), Dr. Wilbur assumes a mean period of five years, and states that "for convenience, comparison of births may well be made with the marriages of the preceding five-year period, and with little sacrifice of accuracy." The mean period for the foreign born is slightly longer than that for the native born.

Assuming a five-year period for Massachusetts, the fecundity for all marriages is as follows:—

For those which occurred in the period 1851-55 = 2.8 children per marriage. For those which occurred in the period 1856-60 = 2.7 children per marriage. For those which occurred in the period 1861-65 = 3.1 children per marriage. For those which occurred in the period 1866-70 = 3.0 children per marriage. For those which occurred in the period 1871-75 = 2.7 children per marriage. For those which occurred in the period 1876-80 = 3.5 children per marriage. For those which occurred in the period 1881-85 = 3.1 children per marriage. For those which occurred in the period 1881-85 = 3.1 children per marriage.

These figures do not exactly express the fertility of all child-bearing women, since a small ratio of illegitimate children are included in the living births whose mothers are not represented in the marriages. The difference in the result in Massachusetts would, however, be very slight, affecting the figures, mostly, only in the second place of decimals.

The fecundity of the native and of the foreign born differs very greatly, as is shown by the following table, which presents the ratio of births in each census year, as compared with the marriages at a census five years earlier:—

| TARLE | 18 | Fecundita | of | the | Marriages | in | Census | Vears |
|-------|----|------------|----|-----|-----------|-----|--------|---------|
| LADLE | 10 | 1 counting | U | unc | muiringes | 676 | Census | 1 curs. |

| | | | | | | CHILDREN BORN T | o Each Marriage. |
|--|-----|-----|-----|--|---|-----------------|--|
| | YEA | RS. | | | | Native. | Foreign. |
| | | | | | | 2.5 | 5.0 |
| | | | | | | 2.4 | 3.7 |
| | | | | | | 1.9 | 3.5 |
| | | | | | | 2.1 | 4.5 |
| | | | | | | 2.2 | 4.4 |
| | | | . • | | . | 2.4 | 4.4 |
| | | | • | | | 2.2 | 5.0 |
| | | | | | | 2.4 | 5.0 |
| | | | | | | 2.4 | 4.3 |
| | | | | | | | YEARS. Native. 2.5 2.4 1.9 2.1 2.2 2.4 2.4 2.4 2.4 2.4 2.4 2.4 2.4 |

This method is not quite so accurate as the comparison of groups of years, but the approximate mean of the two columns, 2.3 for native marriages and 4.4 for those of the foreign born, shows that the number of children in the latter class is nearly twice that of the former.

A population with only 2.3 children to each married couple is not holding its own, after allowing for the deaths which occur in the first five years of life.

BIRTHS.

The whole number of living births registered in 1895 was 67,545. This number was larger than that of any previous year. It exceeded the births of the previous year by 609, and those of 1893 by 353. It was also greater than those of 1885 by 18,755. It exceeded those of 1875 by 23,549, and was considerably more than double the number which occurred in 1865.

The number of births in each 1,000 of the living population in 1895 was 27.02. This birth-rate was less than that of either of the four immediately preceding years but greater than that of any other year since 1874.

Comparing the birth-rates of the two twenty-year periods, 1856-75 and 1876-95, the birth-rates were 27.11 per 1,000 for the former period and 25.86 for the latter, — the difference being 1.25 per 1,000 in favor of the former.

The birth-rates of successive five-year periods, beginning with 1856-60, were as follows: 29.51, 25.34, 26.07, 27.62, 24.25, 25.09, 25.86 and 27.62.

The following table presents the numbers of living births and the birth-rates for each year, together with the birth-rates of five-year, ten-year and twenty-year periods. The numbers for earlier years may be found in the table on page 721.

Table 19. — Births and Birth-rates, Massachusetts, 1856-95.

Sex. — Of the whole number of living children born in 1895, 34,623 were males and 32,905 were females, indicating a ratio of 1,052 males to 1,000 females.

The following were the numbers by sexes for the five years 1891-95:—

Table 20. — Births by Sexes, 1891-95.

| | | YEARS | 8. | | | Males. | Females. | Males to 1,000 Females. |
|-------|------|-------|----|--|---|--------|----------|----------------------------|
| 1891, | | | | | | 32,532 | 30,434 | 1,069 |
| 1892, | | | | | | 33,758 | 31,951 | 1,057 |
| 1893, | | | | | . | 34,328 | 32,829 | 1.046 |
| 1894, | | | | | | 34,338 | 32,575 | 1,054 |
| 1895, | | | | | | 34,623 | 32,905 | 1,052 |

For the two twenty-year periods 1856-75 and 1876-95 the totals and means were as follows:—

Table 21. — Births by Sexes, 1856-95.

| | : | Period | s. | | Males. | Females. | Males to 1,000 Females. |
|----------|---|--------|----|--|---------|----------|----------------------------|
| 1856-75, | | | | | 375,324 | 354,466 | 1,059 |
| 1876–95, | | | | | 515,185 | 489,468 | 1,053 |

The births whereof the sex was unknown are excluded from the foregoing summary. They constituted less than one-fifth of one per cent. of the whole number.

The ratio of males to females for all actual conceptions would be slightly higher than those presented above, since the ratio of males to females among the still-born is usually much higher than that of living births. For example, for the year 1895 the ratio of males to females among all births, living and dead, was 1,066 instead of 1,052, as expressed in the table. The ratio for the whole period of forty years was also 1,066 males to 1,000 females for all births, living and dead.

Other Countries.

The following figures show the relation of the sexes at birth in different countries for a ten-year period (1871-80):—

Table 22. — Births of Males to 1,000 Females.

^{*} The figures for the German Empire are for the years 1872-80.

The foregoing figures are the average results of over 50,000,000 births which occurred in the countries named.

Seasons. — The number of births in each month during the two periods 1856-75 and 1876-95, together with the daily number of births in each month and the monthly ratio reduced to a standard of 100, is

[†] Still-births not included in the figures for England, which probably accounts for its difference from the other figures.

[†] The statistics for Massachusetts are for the forty years 1856-95.

shown in the following table, wherein it appears that the greatest daily number occurred in August in each period and the least in January in the first period and in May in the second.

For the single year 1895 the monthly ratios upon a standard of 100 were as follows: First six months, 101.2, 101.7, 94.8, 90.7, 95.3, 98.5; second six months, 103.3, 104.9, 105.3, 102.7, 98.4, 102.9.

The mean daily number for the year was 185.04.

| Daily number, | 100.03 | 143.7 | - | - | - | - | - | - |

Table 23. - Births by Months, 1856-95.

The mean daily number of births in the first period, 1856-75, was 100.03 and that of the second period was 143.7.

Comparing the two extreme years, 1856 and 1895, the mean daily number had nearly doubled, the figures being 94.1 per day in 1856 and 185.04 in 1895.

The relative excess of births in the last half of the year over the first half had diminished in the following ratio:—

For each 1,000 births in the first half of the year there were 1,138 births in the last half for the twenty years 1856-75, and for the twenty years 1876 to 1895 there were 1,000 births in the first half to 1,071 births in the last half (in equal periods of time).

Births by Parent Nativity. — Since the gross numbers of births of the native and the foreign population of the State, with the percentages of each to the total number of births, convey no correct idea of the birth-rates of these groups of the population, they are omitted in the following table, and the births of the native and foreign population are compared in each instance with the living population of each group as found by census enumeration.

In the following table the births of mixed parentage are equally distributed between those of native and those of foreign birth; the numbers of children having native mothers and foreign fathers and those of children having foreign mothers and native fathers are nearly equal. A small percentage of births of unknown parentage is excluded from the table.

Table 24. - Births and Birth-rates by Parent Nativity, Massachusetts.

| 1875, . | | 1,225,829 | 418,904 | 20,228 | 23,203 | 16.50 | 55.40 |
| 1880 | | 1,339,594 | 443,491 | 21,722 | 21,243 | 16.22 | 47.90 |
| 1885 | | 1,415,274 | 526,867 | 23,258 | 24,169 | 16.43 | 45.87 |
| 1890, . | | 1,581,806 | 657,137 | 26,084 | 31,422 | 16.49 | 47.82 |
| 1895 | | 1,735,253 | 764,930 | 28,774 | 38,551 | 16.58 | 50.40 |

These enormous differences in the birth-rate of the native and the foreign population must be considered in connection with two or more limiting facts. First, the age constitution of the foreign population is quite different from that of the native population, since, as was shown under the section relating to marriages (page 728), the former contains a greater ratio of persons of child-bearing ages. Second, the race constitution of the native and foreign populations is quite different, the latter being composed very largely of persons from countries where the birth-rate is high. The continuous immigration of French Canadians of adult, child-bearing ages has had an undoubted effect upon the birth-rate.

The population enumerated in the different censuses as being of British-American birth had increased from 21,707 in 1855 to 147,352 in 1885, and of the latter, 64,503 were French Canadians.*

Plural Births. — In 1895 the number of cases of plural birth was 745, of which 736 were cases of twin births and 9 were cases of triplets, the whole number of children born in such plural births being 1,499, of which 773 were males and 726 were females.

This was equivalent to the following ratios: 1.09 per cent. for cases of twins, or 1 case to 92 living births, and .013 per cent. for cases of triplets, or 1 case to each 7,505 living births.

For the two twenty-year periods the figures were as follows: -

| PERIODS. | Ali Births. | Cases of Twins. | Cases of Triplets. | Percentage of Twin Births. | Percentage of Triplet Births. | Living Births to One Case of Twins. | Living Births to One Case of Triplets. |
|----------|----------------------|-----------------------|--------------------------|----------------------------------|-------------------------------------|---|--|
| 1856-75, | 731,335 1,049,537 | 6,852 9,450 | 76 109 | 0.94 | .013 | 106.7 111.1 | 9,623 9,629 |

TABLE 25. — Plural Births, 1856-95.

The foregoing figures are derived from more than one and three-fourths million births which occurred in Massachusetts in the forty years 1856-95. They may be compared with the statistics of about twenty million births which occurred in the following countries, mostly during the ten years 1874-83:—

| TABLE | 26.— | Ratio | of | Plural | Births. |

ABLE 27. — Living Births and Still-births, 1856-95.

The deaths of males to those of females, among the still-born infants whose sex was known, in the first period, maintained the ratio of 1,501 males to 1,000 females, and in the second period 1,489 males to 1,000 females.

The recorded fatality for each sex was greater in the second period than it was in the first, being for males 2.95 per cent. of all recorded births of males living or dead, in the first period, and 3.78 in the second, and for females 2.10 per cent. in the first and 3.26 in the second.

The mean percentage of the whole period for males was 3.42 and for females 2.45, and for both sexes 2.96, the latter being the ratio of 52,858 still-births to 1,787,301 births living and dead, of those whose sex was known.

In the first period there were 1,589 still-births the sex of which was not registered, or 7.7 per cent. of the whole number of still-births registered in that period. In the second period there were 1,558 of this class, or 4.6 of the whole number. This reduction, not only in the relative but also in the absolute figures, may be taken as an indication of more perfect registration, and probably furnishes a partial explanation of the increased percentage of the still-born in the second period as compared with the first.

The still-births registered in 1895 were 2,367, of which number 1,423 were males, 892 were females, and the sex of 52 was not stated.

Italy,

3.02

The death-rate of the still-born among illegitimates is usually from 10 to 30 per cent. higher than that of legitimate infants.

Illegitimacy.

The record of illegitimacy in Massachusetts must be more or less incomplete, because under existing laws there is no requirement that the certificate shall contain the facts as to legitimacy or illegitimacy. A partial clue to the solution of this question exists in the names of the parents, which must be recorded. The tendency of legislation in this direction does not appear to improve the accuracy of the record. Moreover, a considerable number of births occurs in each year in which the parentage is unknown, or not stated in the record. presumption is that most of these births are illegitimate.

With these facts in view the following figures are presented, for the period 1856-91.

During the first twenty years of the period, from 10 to 25 per cent. of the recorded illegitimate births occurred in the three State almshouses at Tewksbury, Bridgewater and Monson. should be added, in the second period, a small number at the Reformatory Prison for Women. The relative number of such births at public institutions was less in the second period than in the first. The unusual ratio recorded in Suffolk County is due to a larger number of such births in the public charitable and correctional institutions of Boston.

^{*} Die Bewegung der Bevölkerung in der Schweiz. Bern.

Table 29. — Illegitimate Births in Massachusetts, 1856-91.

If any reliance can be placed in these figures, illegitimacy has increased considerably in Massachusetts, comparing the two periods, that of the first being as 9.3 per 1,000 births and that of the second period as 18.5 per 1,000.

On account of the defective character of the returns upon this point for the years 1892, 1893, 1894 and 1895, the figures of these years are omitted from the foregoing table, and the total number of illegitimate births at the bottom of the column (14,485) and the ratio (18.5) are for the sixteen years ending with 1891.

Sex. — In the twenty years 1856-75 there were registered 3,294 births of illegitimate males and 3,472 of females, or in the ratio of 1,054 females to 1,000 males. The sex of 39 was unknown.

In the twenty years 1876-95 there were registered 8,820 births of illegitimate males and 8,302 of females, and the sex of 33 was unknown, or in the ratio of 941 females to 1,000 males.

The following table presents the illegitimate birth-rates deduced from over thirty million births in the countries named:—

^{*} Die Bewegung der Bevölkerung in der Schweiz. Bern.

DEATHS.

The number of deaths registered in 1895 was 47,450. This was greater than the number registered in 1894 by 659, but was less than those of 1892 or 1893. The death-rate per 1,000 of the living population was 19.01, which was less than that of any previous year since 1879, except that of 1886, which was 18.64 per 1,000.

Comparing the death-rates of the two twenty-year periods, 1856-75 and 1876-95, the death-rates were nearly identical, or 19.49 for the former and 19.51 per 1,000 for the latter period, the difference being only .02.

The death-rates of the successive five-year periods were as follows: 17.94, 20.71, 18.19, 20.83, 18.84, 19.82, 19.41 and 19.83.

The following table presents the deaths and death-rates for each year from 1856 to 1895 inclusive, together with the death-rates for the five-year, ten-year and twenty-year periods. The numbers for earlier years may be found in the table on page 721.

Table 31. — Deaths and Death-rates, 1856-95, Massachusetts.

The course of the death-rate from year to year is shown in the foregoing table and in the diagram on page 712. In the table the year 1872 is shown to have had an unusually high death-rate, a fact which appears upon inspection to have been due to the prevalence of several infectious diseases as epidemics.

In that year small-pox caused a death-rate of 6.7 per 10,000, which was more than four times greater than the mean death-rate of the twenty-year period from this cause, and was also much the highest of the whole period of forty years. The death-rate from measles was also nearly double the mean of the twenty-year period, and greater than that of any year of the forty-year period except one. The death-rate from scarlet-fever was a little greater than the mean of the twenty years. That of typhoid fever was greater than that of any year except two in the forty years. That of cholera infantum was double the mean of the twenty-year period, and the greatest of any year in the entire forty years. That of pneumonia was also greater than the death-rate of any year of the twenty-year period except one.

Such a year was also 1849, in a still earlier period, when the death-rate, even with more imperfect registration, amounted to 21.16 per 1,000.

In that year diarrheal diseases (including 1,188 registered as from Asiatic cholera) produced a death-rate of 46.0 per 10,000 living, and amounted to 21.7 per cent. of the total mortality, as compared with a mean of less than 10 per cent. in the forty years 1856-95. Dysentery in that year attained the enormous death-rate of 25.4 per 10,000 living, a mortality far beyond that of any year in the whole period of registration from this cause. The deaths registered as from dysentery in that year were more than the entire number registered from the same cause in the previous seven years of registration.

Deaths by Sexes. — The number of registered deaths of males in 1895 was 24,175, and that of females was 23,365.

The death-rate of males was 19.91 and that of females was 18.18 per 1,000 of the living population of each sex.

The following table presents the mortality of the sexes during the census years 1860-95:—

| | YEARS. | | Deaths of Males. | Deaths of Females. | Death-rate of Males. | Death-rate of Females. | Deaths of Males t 1,000 Deaths of Females in Equa Numbers Living |
|---------|--------|---|------------------|--------------------|----------------------|------------------------|---|
| 1860, . | | | 11,444 | 11,547 | 19.3 | 18.4 | 1,048 |

| 1895, . | | | 24,175 | 23,365 | 19.9 | 18.2 | 1,095 |

Table 32. — Mortality of the Sexes in Census Years, 1860-95.

The disparity between the death-rates of the sexes in Massachusetts was generally less than that of England, which was as 1,121 deaths of males to 1,000 deaths of females in equal numbers living for 1894, and as 1,103 to 1,000 for the whole period of registration, 1838–94.

Deaths by Seasons. — In the following table are presented the statistics of deaths by months and by sexes in Massachusetts for the year 1895:—

Table 33. — Mortality by Months, Massachusetts, 1895.

^{*} In column 5 100 is taken as the annual mean for a monthly period of uniform length.

In the foregoing table, in the figures presented in columns 5 and 6 the inaccuracies due to the unequal length of the months have been eliminated by comparing the daily number of deaths in each month with the mean daily number for the year. It is also quite plain that an estimate of population which may be applied in calculating the death-rate in January and February cannot reasonably be applied to the same purpose in November and December, since the annual increase of the population, amounting in recent years to about 60,000 annually, is thus disregarded. Hence, in estimating the death-rates given in column 4, a quarterly estimate has been adopted based upon the rate of growth from 1890 to 1895, after the method adopted by the Registrar General of England in his weekly reports. By this table it appears that the highest daily number of deaths occurred in February, and the next highest in August and in March, and the least daily number occurred in June, November and May.

The percentages of deaths in each quarter of the year were as follows:—

| In the first quarter, | | | | | 27.40 |
|------------------------|--|--|--|---|--------|
| In the second quarter, | | | | | 22.47 |
| In the third quarter, | | | | | 26.94 |
| In the fourth quarter, | | | | | 23.19 |
| | | | | - | |
| | | | | | 100.00 |

Deaths by Months for Two Twenty-year Periods. — In the following table are presented the deaths by months for the two twenty-year periods 1856-75 and 1876-95:—

Table 34. — Deaths by Months, 1856-95, with Relative Figures for Other Countries.

| Total, | 525,118 | 791,754 | | | - | - | - | - | - | |
| Mean, | 71.9 | 108.4 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | |

^{*} The figures for other countries are the result of observations upon over seventeen million deaths registered in the countries named.

By the foregoing table it appears that in the first twenty-year period the mean daily number of deaths was 71.9 and in the second period 108.4. The months in which the deaths were above the mean were July, August and September in the first period, and January, February, March, April, July, August and September in the second period. In the first period the deaths in the first half of the years compared with those in the last half were as 1,000 to 1,163, and in the second period as 1,000 to 1,045 (in equal periods of time).

Nativity. — Since no statement of deaths by nativity appears in the registration reports until 1888, the deaths and death-rates of the native and foreign population are only presented for the years 1888-95.

The populations of each group are also given, with estimates for the intercensal years.

Table 35. — Population, Deaths and Death-rates, Native and Foreign, for the Years 1888-95.

| | | | POPULATION. | | DEAT | THS. | DEATH-RATES. | | |
|---|----|--|--|--|--|--|--|--|--|
| YEAR | 3. | Native. | Foreign. | Total. | Native. | Foreign. | Native. | Foreign. | |
| 1888, 1889, 1890, 1891, 1892, 1893, 1894, | | 1,513,273 1,547,214 1,581,806 1,611,437 1,641,590 1,672,271 1,703,490 1,735,253 | 601,863 628,945 657,187 677,474 698,403 719,945 742,114 764,930 | 2,115,136 2,176,159 2,238,943 2,288,911 2,389,993 2,392,216 2,445,604 2,500,183 | 31,124 30,650 31,605 32,733 35,097 35,285 34,301 34,472 | 10,574 10,687 11,508 11,907 13,044 13,136 11,895 12,515 | 20.6 19.8 20.0 20.3 21.4 21.1 20.1 19.9 | 17.6 17.0 17.5 17.6 18.7 18.3 16.0 16.4 | |
| | | | | | 265,267 | 95,266 | 20.4 | 17. | |

The foregoing table shows that the death-rate of the foreign population for the eight years was less in each year than that of the native population, the mean difference for the whole period 1888-95 being 3 in each 1,000 living.

This difference may be partly accounted for by the difference in the age constitution of these two groups of the population, as was stated under the section relating to marriages. The same difference which would produce an increased marriage and birth rate would also produce a diminished death-rate, other things being equal.

Density of Population.

It was shown in the early reports of the Registrar-General of England that the death-rate of communities bears a definite relation to the density of population. The area of a state or county remaining constant, as the population increases the density increases. The proximity of persons to each other and their consequent liability to communicate infectious diseases increase with the density.

In the following table the population of the State is divided into two groups of counties, which may be properly called urban and rural groups. The former contains 56 cities and towns, each having a population of more than 5,000 (census of 1895); the latter has 29 such places.

Nearly nine-tenths of the inhabitants of the former group live in these populous cities and towns, while the population of the latter group living in such places is less than half of the population of the group.

Table 36.— Relation of the Death-rate to Density of Population, by Groups of Counties, 1895.

| | THE STATE | , . | | | | | 8,315 | 301 | 2,500,183 | 47,540 | 19.0 |

In the accompanying table the density is expressed by the average number of persons living upon each square mile of area. The same might also be expressed in terms of acres to each person, as in the twenty-third annual report (paper on "Geographical Distribution of Disease").

The density has increased as follows: -

Table 37. — Density of Population, 1860-95.

Note. — In the supplement to the twenty-fifth annual report of the Registrar-General of England, Dr. Farr gives a definite statement of the relation which subsists between the density of population and the deathrate, which is briefly as follows, as determined by observation, dividing the population into five groups:—

"1. Where the death-rate was 14, 15 or 16 per 1,000 the density of the population averaged 86 persons per square mile.

"2. Where the death-rate was 17, 18 or 19 per 1,000 the population was 172 per square mile.

"3. Where the death-rate was 20, 21 or 22 per 1,000 the population was 255 per square mile.

"4. Where the death-rate was 23, 24 or 25 per 1,000 the population was 1,128 per square mile.

"5. Where the death-rate was 26 and upwards the density of the population averaged 3,399 persons per square mile."

In 1855 Massachusetts held a position as regards density about midway between the first and second of the foregoing groups (the density then being 136 per square mile), while in 1895 it had advanced to a position between the third and fourth groups (with a density of 300 per square mile). Yet during these four decades the death-rate remained practically the same, — 19.4, 19.6, 19.4, 19.6,—a fact that may be taken to show that improved sanitary conditions have very nearly counterbalanced the unfavorable influence of increasing density.

Deaths by Ages.

The mortality at different ages constitutes an important index of the sanitary condition of a community and hence requires careful consideration.

"As tests of the sanitary condition, the death-rates of infants under one year and of children under five years of age are more important than the rates at any other groups of ages. Investigation has shown beyond doubt that the ages of young children are very incorrectly returned at the census enumeration, owing to the general and indiscriminate use of two methods for describing age. At the census enumerations the numbers of infants under one year of age are understated." (Memorial volume on "Vital Statistics," London, 1885, page 114.)

The foregoing comment by Dr. Farr applies with equal justice to each of the enumerations of the United States census and to those of Massachusetts. (See report of the Board for 1894, page liv.)

Hence, in the following table the infantile death-rate is not calculated upon the census figures for living children under one year but upon the registered births, in accordance with the method advised by Dr. Chalmers in his "New Life-table of Glasgow," page 14.

No attempt has been made to carry this estimate beyond the fifth year of life, since the disturbing effect of migration seriously affects the accuracy of any calculation upon this basis when applied to a rapidly increasing New England community. The newly arrived foreign-born infants in the first year of life constitute less than 1 per cent. of the children of that age, and the foreign-born children among those under five years of age constitute less than 4 per cent. of all children of that age; but the foreign born among the population from thirty to fifty years of age constitute fully 40 per cent. of the population of those ages. It is chiefly for this reason that the construction of an accurate life-table from the population and mortality tables of an American State is rendered practically impossible.

Table 38. — Infant Mortality, Massachusetts, 1856-95, Forty Years.

Mean of whole period, 156.7.

Strictly speaking, the death-rate of infants under one year is obtained by comparing the deaths of such infants occurring in a year with the mean number of infants under one living throughout a year, and this number must "lie between the annual number of births and that number diminished by the deaths under one. It would be nearer the latter than the former number on account of the excess of deaths in the first months of life." (Dr. Farr.)

For the sake of uniformity in comparison with the statistics of other states and countries, the deaths under one are here compared with the births. In the foregoing table the births in the first line (1856) are those which occurred between July 1, 1855, and June 30, 1856, inclusive, and so on through the table, the births in the last line being for the year ending June 30, 1895.

The deaths under one in the same table are those of the calendar years ending Dec. 31, 1856, 1857, etc. The births in this whole period were 1,762,874, and the deaths under one year were 276,260, which is equivalent to a death-rate of 156.7 per 1,000 living births, as a mean of the whole period.

Dividing the whole time into ten and twenty year periods, the infantile death-rate of the first twenty years was 150.3 and that of the second twenty years was 161.2 per 1,000 births. The difference in the rates of the ten-year periods is much greater, chiefly on account of the disturbing effect of the epidemic years 1872 and 1873, when cholera infantum prevailed to an unusual degree. The infantile death-rates of the four ten-year periods were, respectively, 134.2, 164.2, 157.8, 163.6. By this it appears that the infantile death-rate has increased considerably when we compare the first twenty years with the last twenty, and especially when the first and last ten years are compared. If the figures for the two years 1872 and 1873 were to be omitted from the table, the infantile death-rate of the remaining eight years in the ten-year period 1866-75 would be reduced to 156.5.

The death-rate of infants under one has diminished with considerable uniformity during the last five years (1891-95) from 169.0 per 1,000 births in 1891 to 158.2 in 1895.

Infant Mortality of Cities.

For the purpose of presenting the infant mortality of the cities of Massachusetts, a ten-year period has been selected, and since only eleven ont of the thirty-two cities embraced in this summary existed as incorporated cities at the beginning of the period under consideration, the ten years 1881–90 are selected for examination. The later ten-year period 1886–95 would have been selected, but unfortunately the presentation of the deaths by ages in the different cities in the State appears to have been abandoned in the registration reports since 1890.

In the following table the cities are arranged with reference to their comparative rank so far as infant mortality is concerned.

Of the first seven cities in this table all except Boston are cities in which the cotton and woollen industries largely predominate. In the first three the tenement-house population is also unusually large.

In the twenty-third report of the Board, page 836, attention was also called to the fact that the mortality from cholera infantum, which is one of the chief factors of the death-rate under one year, bears a direct relation to the ratio of married women employed away from their homes, and this ratio reaches its maximum in Fall River, where this class constitutes 3.1 per cent. of the total population.

There are also several smaller towns, not included in this list (Webster, Ware, Adams and Millbury), in which the same class of manufactures is conducted, and which have a considerable tenement-house population, with a high rate of infant mortality.

The cities of Haverhill, Marlborough, Brockton and Lynn, each having an infantile death-rate below that of the State at large, are all shoe manufacturing towns, in which the tenement-house population is comparatively small.

Near the bottom of the list are the cities of Malden, Everett, Medford and Newton, in which the residential population largely predominates. The manufacturing population constitutes but a small fraction, and the infantile death-rate is much less than that of the State.

The death-rate of infants for the State at large was 160 per 1,000 births, while that of the combined urban population was 175 per 1,000 and that of the rural population was 129.

Table 39. — Infant Mortality of Cities, Ten Years, 1881-90.

| | | | Births. | Deaths, 0-1. | Infantile Mortality * | Rank, the State = 100. |

^{*} Deaths of infants under one year per 1,000 births.

Passing on to the next years of childhood, and employing the method advised by Dr. Chalmers for the whole period of forty years, the death-rates are as follow:—

Table 40. — Death-rate per 1,000 Living at Same Ages.

| | | | | | | _ | PER | iods. |
|------------|--|---|------|--|--|-----|----------|----------|
| | | A | GES. | | | | 1856-75. | 1876-95. |
| 1-2 years, | | | | | | | 67.9 | 54.3 |
| 2-3 years, | | | | | | | 36.0 | 28.4 |
| 3-4 years, | | | | | | . | 24.5 | 20.5 |
| 4-5 years, | | | | | | . 1 | 18.8 | 15.6 |

From these figures it appears that certain interesting changes have taken place in the mortality of children in Massachusetts during the forty years under consideration. The death-rate of infants under one year is greater now than it was in the first half of the period, but the death-rate of children from one to five years is less than it was then.

The probability that an infant under one year old will complete its first year of life is less at the present day than it was in the first half of the period, but, having survived his first year of life, his chance of completing the next four years is considerably greater than it then was. A discussion of some of the conditions contributing to these changes will be found on a later page, under the title "The Balance of Mortality."

The infantile death-rate differs much in different countries, since in some communities it amounts to as much as one-third of the births and in others it is not more than one-tenth.

The following table presents the infantile death-rate, as stated by Dr. Eross in a recent paper in Koch's "Zeitschrift f. Hygiene" (Vol. 19, 1896, page 371):—

Table 41. — Infant Mortality, Deaths under One per 1,000 Births.

| Countri | ES. | | Years. | Infant Mortality per 1,000 Births. | COUNTRIES. | | Years. | Infant Mortality per 1,000 Births. |
|-------------|-----|---|---------|--|-----------------|---|---------|--|
| Ireland, . | | | 1884-88 | 94 | Italy, | | 1884-91 | 192 |
| Sweden, . | | | 1881-90 | . 97 | Prussla, | ٠ | 1886-92 | 207 |
| Scotland, . | | | 1885-90 | 120 | Hungary, | | 1884-87 | 212 |
| England, . | | | 1885-91 | 144 | Austria, | | 1886-87 | 246 |
| Belgium, . | | | 1881-91 | 159 | Saxony, | | 1886-92 | 281 |
| France, . | | | 1885-90 | 165 | Bavaria, | | 1879-88 | 287 |
| Holland, . | | ٠ | 1885-90 | 179 | Massachusetts,. | | 1876-95 | 161 |

Dr. Schlossmann states the importance of this portion of the subject very tersely as follows: "The death of every child constitutes a definite loss of national wealth" ("Zeitschrift f. Hygiene," Vol. 24, page 19).

For the remaining age periods (five to ten years and upward) the following table may be consulted (page 756). In this table the column published in the registration report of 1890, page 294, "under one," is omitted in consequence of the serious defects in the census for children of that age. (See report of State Board of Health of 1894, page liv.) For the succeeding years up to age forty there has been a decrease in the death-rate at each period of life, as follows, comparing the figures of 1865 with those of 1895:—

Table 42. - Death-rates per 1,000 Living at Certain Age Periods, 1865 and 1895.

| | | Y | EARS, | | 5-9. | 10-14. | 15-19. | 20-29. | 30-39. |
|----------------|---|---|-------|--|------|--------|--------|--------|--------|
| 1865, 1895, | • | | | | 9.63 | 5.14 | 9.63 | 12.58 | |
| 1895, | | | | | 6.23 | 3.18 | 5.34 | 7.08 | 9.67 |

On the other hand, the later ages of life present in each instance an increase in the death-rate, as follows:—

Table 43. — Death-rates per 1,000 Living at Certain Age Periods, 1865 and 1895.

| | YEARS. | | | 40-49. | 50-59. | 60-69. | 70-79. | 80 and Over. |
|--------------------|--------|--|---|--------|--------|--------|--------|--------------|
| 1865, . | | | | 11.86 | 17.49 | 32.90 | 70.48 | 168.23 |
| 1865, . 1895, . | | | ٠ | 12.65 | 20.45 | 39.37 | 82.41 | 184.65 |

These figures show that while no very decided changes have taken place in the general death-rate during forty years (that of the first twenty years being 19.49 and that of the last twenty 19.51) very marked changes have taken place in the death-rates at different ages.

The causes and conditions under which these changes have taken place will be more fully considered under the head of "The Balance of Mortality," following the discussion of the "Causes of Death."

Table 44. - Population, Deaths and Death-rates per 1,000 Living at Specified Ages, 1865-95.

Note. — The table on page 756 cannot be considered as an accurate table, from which precise conclusions can be drawn. Its chief merit lies in the fact that the figures selected for presentation are those of census years and hence more accurate than those which are estimated in the intervening years. The serious defect of the table consists in the fact that single years may at any time present unusual departures from the mean of a series. Thus in this table, 1865 was a year of unusually high death-rate, being much above the mean of the forty years 1856–95, and the death-rate of 1895 was also considerably below the mean. A much better method is that of comparing continuous series of years, as in tables 8, 19 and 31.

Causes of Death.

It has been the custom in earlier summaries of the mortality of different countries to attach considerable importance to the broad and general groupings or classes of disease and causes of death; but in later years, and especially in many of the best foreign reports upon vital statistics, greater stress has been laid upon the presentation of diseases separately, without regard to their relation to each other. In the recent reports of the registration officer of Michigan a provisional classification has been adopted for temporary use, subject to such modification as medical progress may demand.

These changes have become necessary in consequence of the rapid advances in medicine, and in the knowledge of the causes and natural history of disease. As evidence of this may be cited the introduction of the term "diphtheria" in 1858 (a disease well known and observed before under other complex names), the separation of typhus from typhoid fever, the disuse of such meaningless names as nephria, metria, noma, etc., the gradual disuse of the term "zymotic," and the transfer of tuberculosis to a place among infectious diseases.

These considerations have more weight in the present summary (which embraces the statistics of forty years) than in the ordinary digest of the statistics of a single year.

In proof of the decided changes which have taken place in the mortality from different causes during the forty years under consideration the following table is presented, in which is shown the comparative order of fatality of the ten most destructive causes and groups of causes of death for the first and last ten years of the whole period. These two series of years are selected for the purpose of presenting the conditions prevailing at the beginning and close of

the period. For the same reasons the order of the years in the upper portion of the table is the reverse of that in the lower, in order that the two extreme years of the period (1856 and 1895) may be shown in contrast.

One circumstance which is clearly indicated by the figures in this table is the decidedly greater prevalence of epidemics in the former period as compared with the latter. This is indicated by the marked irregularity in the order of the figures in the columns representing the first ten years.

An examination of Table 45 and of those on pages 762 and 764 shows that consumption has from the outset maintained the first place as the most destructive cause of death. The uniform diminution, however, in the mortality from this cause gives good reason for believing that in a very few years it will have disappeared from the head of the column. In 1856 the deaths from consumption were nearly four times as many as those of the next cause upon the list, while in 1895 the deaths from consumption exceeded those of the next destructive group of causes by a little more than 5 per cent. only.

A glance at the order of the figures in the two columns headed 1856 and 1865 shows that much more decided changes in the order of fatality had taken place in the early period than had occurred in the later period, comparing the columns for 1886 and 1895.

During the intervening period (1866-85) changes were still in progress, consumption maintaining the first place, and in one year (1872) only did small-pox attain sufficient importance to find a place in the table as the ninth cause in the order of destructiveness.

Croup was, during the first two years, the tenth cause, and diphtheria appears for the first time in 1858, and from that date eroup and diphtheria are considered together. This group rapidly rose in its order of destructiveness from the tenth in 1856 to the second place in 1863 and 1864. A similar sudden accession of virulence occurred between 1872 and 1876, when diphtheria alone appears to have risen from the nineteenth place to the second in the course of five years. (See registration report of 1876, page 54.)

Another important change is that in the mortality from pneumonia, which has risen during the whole period from the fifth place in 1856 and 1857 to the third place in each year of the entire period 1886–95, except 1893, when it was second in rank. This change, too, has been comparatively uniform, though not so steadily maintained as the downward tendency in consumption.

Scarlet-fever, dysentery and typhoid fever have disappeared from the list, and their places are supplied by cancer, kidney diseases and bronchitis.

Further information in regard to these changes may be found under the title "The Balance of Mortality."

Deaths from Unknown or Unspecified Causes.

Under the term "causes not specified" it has been the custom to include all deaths certified as from hemorrhage, tumor, inflammation and cause unknown. Owing to changes in the methods of tabulation the number of deaths referred to this title, "causes not specified," was increased from 478 and a percentage of 2.1 of the total mortality in 1867, to 1,464 and a percentage of 5.7 in 1868. From the latter date down to 1895 there has been a comparatively uniform improvement, the percentages of this class being as follows for the successive years 1891-95: .90, .96, 1.1, 1.0 and .94.

While these figures represent an improvement, they do not show the serious defects which exist in the certification and tabulation of other deaths. These questions have been discussed by the Massachusetts Association of Boards of Health, and a partial method of relief was suggested, consisting in the modification of the present form of death certificate in such a manner as to convey to the certifying physician such information as would lead him to take greater pains in registering the cause of death with accuracy and sufficient fulness of detail.

As an example, the following terms convey but little accurate information, and in many cases wrong conclusions must be drawn from the mass of recorded facts. In 1895 there were 163 deaths recorded as from septicemia (no clue to its character being given), 88 from dropsy, 153 from mortification, 1,451 from cephalitis, 903 from cancer (the location being omitted), 703 from peritonitis, 1,163 infantile and premature, and 1,199 from atrophy and debility. These deaths, together with the 445 classed as from cause not specified, constitute more than 13 per cent. of all the deaths of that year, and while it is undoubtedly true that the causes of many deaths must necessarily be recorded in an indefinite manner, it is plain that great improvement is possible by more accurate certification, as well as by the system pursued by the British Registrar-General, and by the registration authorities of many states, of subjecting all doubtful returns to careful revision.

In the table on page 767 the deaths and death-rates presented in Table 46 are given in five-year periods, the percentages of total mortality being omitted.

SUMMARY OF CERTAIN SPECIAL CAUSES OF DEATH PRESENTED IN THE FOREGOING TABLES.

For the sake of uniformity the same order will be observed in this discussion as that which was adopted in the reports of the Board for the last two years, with the addition of dysentery and child-birth. The terms "first and second period" or "first and last period" refer in each instance to the two twenty-year periods 1856-75 and 1876-95, unless otherwise specified. The term "death-rate" in this discussion of causes of death means the ratio of deaths per 10,000 of the living population, unless otherwise specified. When the term "general death-rate" is employed it means the death-rate from all causes, and is reckoned as a ratio per 1,000 of the living population. (For a full discussion of the mortality from measles, scarlet-fever, diphtheria and croup, small-pox, typhoid fever, cholera infantum, phthisis and pneumonia, with reference to their geographical distribution, with maps, see twenty-third annual report of the Board, 1891, pages 759-874.)

Small-pox.

Total deaths, 1856-95, 4,225.

During the seventeenth and eighteenth centuries epidemics of small-pox were of very frequent occurrence in Massachusetts, as historical records present abundant proof. Some of the most noted of these were those of 1631, 1633, 1639, 1677, 1678, 1702, 1721 (in this year nearly 8 per cent. of the whole population of Boston died of small-pox), 1730, 1752, 1764, 1776, 1778 and 1792.

From the date of the introduction of vaccination down to 1840 the mortality from small-pox was extremely small. Records are incomplete for these years, but from all that can be learned it is probable that the total mortality from this cause did not exceed 200 deaths in the State during these forty years. Unfortunately, the vaccination law was modified in 1836 and made less stringent, and the deaths from small-pox soon increased, the number in Boston alone in the three years 1839-41 amounting to 232. After that date the enactment of the registration laws furnished accurate returns for the whole State, and from these it appears that the deaths from this cause from 1842 to 1855 inclusive were 1,304.

No deaths were registered from this cause in 1895 and there were none in 1886.

Of all the causes of death mentioned in the foregoing tables small-pox was the most irregular in its influence on the death-rate, the figures varying from 0 in 1886 and 1895 to 6.7 per 10,000 of the

population in 1872. The mean annual small-pox death-rate of the first twenty years was 1.5 per 10,000 living, and that of the last twenty years was only .07 per 10,000.

The slight discrepancy between the total numbers of deaths from small-pox in tables 46, 48 and 50 is due to the inclusion, in the former table, of 15 deaths registered as due to chicken-pox which are not included in the latter table. It is quite probable that deaths registered as from chicken-pox are those of persons who have died of small-pox, especially when occurring in years of small-pox epidemics.

More than 40 per cent. of the deaths from small-pox which occurred in the forty years 1856-95 were those of the epidemic of 1872 and 1873.

Sex. — The death-rate of males was considerably greater than that of females, being in the ratio of 164 males to 100 females in equal numbers living in the first period, and as 133 males to 100 females in the second period.

Seasonal Mortality.—The deaths from small-pox in the first period of twenty years were most numerous in January and December, and least numerous in August and September. In the second period they were the greatest in number in April and May, and least in July and August.

Ages. — In Table 49 it appears that the greatest small-pox deathrate occurs at the age period 0 to 5 years and the least at the period 10 to 15. A considerable increase occurs at the ages 15 to 40, undoubtedly due to the neglect of revaccination at an age when the protective power of primary vaccination has considerably diminished. (A further discussion upon the mortality from small-pox in Massachusetts, with special reference to the influence of vaccination, may be found in the twenty-sixth annual report of the Board, 1894, pages viii–xxiii.)

Measles.

Deaths, 1856-95, 7,952.

The deaths from measles in 1895 were 117, and the death-rate was .5 per 10,000 of the living population, which was less than the mean of the twenty-year period 1876-95. Comparing the two twenty-year periods, 1856-75 and 1876-95, a decided lessening in the mortality from this cause is evident, that of the former period being 1.6 per 10,000 living and that of the latter .9, or but little more than one-half as great. The total number of deaths from this cause in the former period was 4,299 and in the latter 3,653.

At no time in the first twenty years did the deaths from this cause fall below 100 in a single year, while in the latter period there were six years in which the deaths from measles were as follows: 47, 19, 68, 75, 88 and 98.

The deaths of females were as 100 to 116 males in equal numbers living in the first twenty-year period, and as 100 females to 102 males in the second period.

Seasonal Prevalence.—It appears that in the first period the greatest mortality from this cause occurred in June, and in the second period in May, and the least in October in each period. The second period showed greater departures from the mean than the first period.

Age. — The death-rates from measles at different ages of life are presented in tables 49 and 51. They show marked improvements at all ages of life. The death-rate of children under five was 11.7 per 10,000 in the first period and 8.08 in the second.

A statement of the death-rate* of children at each of the first five years may be found in the report of 1894, page xc, wherein it appears that the greatest death-rate from this cause occurs at age one to two years. A statement of the geographical distribution of measles, with the mortality of each city and town from this cause, may be found in the twenty-third report of the Board (1891), page 780. The highest mortality from this cause was shown to exist in Suffolk County and the lowest in Nantucket.

Scarlet-fever.

Total deaths, 1856-95, 34,485.

The deaths from scarlet-fever in 1895 were 483. This number was less than that of either of the three preceding years, but greater than that of 1889, 1890 or 1891. The deaths from this cause in the first period were 23,797 and those of the second period were 10,688. The mean annual death-rates were, respectively, 8.8 and 2.6 per 10,000 living. In only three years of the first period did the death-rate per 10,000 from this cause fall below 6, while in the second period it exceeded that rate in only one year, and that was 1876, the first year of the period.

Had the same death-rate from scarlet-fever prevailed in the second period, 1876-95, as prevailed in the first period the mortality from scarlet-fever would have amounted to 25,000 more than act-

^{*} The term "death-rate" as here used should not be confounded with "fatality," i. e., the ratio of deaths to cases.

ually occurred in those years, and this number may be taken as the actual saving of life from this cause.

Sex. — The deaths of males to females were as 108 to 100 in equal numbers living in the first period, and as 103 to 100 in the second period.

Seasonal Mortality. — The greatest mortality from scarlet-fever in each period was in January and the least in September.

Age. — The death-rate at different ages shows a rapid decrease from the infantile period (0-5) to the age of 60 years; the highest death-rate at age 0-5 was 54.9 per 10,000 living of those ages in the first period, that of the same age in the second period being 18.41, or about one-third as great.

The death-rate* of children at each of the first years of life from this cause (corrected) may be found in the report of 1894, page xc, wherein it appears that the greatest death-rate from scarlet-fever occurs in the third and fourth years of life.

The marked improvement in the death-rate from this disease since 1856 is shown by the following death-rates of five-year periods:—

Death-rate. Death-rate. PERIOD. PERIOD. 1856-60, 10.5 1876-80, 4.11861-65, 9.7 1881-85, 2.7 1866-70, 6.8 1886-90, 1.7 1871-75, 8.6 1891-95, 2.4

Table 52. — Death-rates from Scarlet-fever, 1856-95.

That the diminution in the death-rate of scarlet-fever indicated by the foregoing figures is not peculiar to Massachusetts may be shown by an examination of the vital statistics of other countries. The following table presents the same data for certain European countries, together with those of Massachusetts for similar periods:—

Table 53. — Decrease in Scarlet-fever in Different Countries.

Death-rates per 10,000 Living at Certain Periods.

The foregoing data are to be found in a paper entitled "A Contribution to the Natural History of Scarlet-fever," by John T. Wilson, M.D., D.Ph., Medical Officer of Health, Lanarkshire, Scotland.

An examination of the reports of health officers of the Australian colonies and New Zealand shows that similar changes in the death-rate from scarlet-fever are also taking place there.

Diphtheria and Croup.

Total deaths, 1856-95, 58,490.

In Table 46 the deaths registered under these terms are considered together.

In 1895 the deaths registered from these causes were 1,784, of which number 1,432 were certified as deaths from diphtheria and 352 as deaths from croup. The death-rate per 10,000 from these combined causes was 7.1, that of 1894 having been 7.4.

The total deaths recorded from these causes in the first twenty-year period were 19,361, and the death-rate 7.2 per 10,000, and those in the last period were 39,129, and the death-rate 9.6 per 10,000.

Dividing the last period into five-year groups there appears to have been a marked diminution, as shown by the following death-rates for the respective periods:—

| 1876-80, | | | | | | | 15.8 |
|----------|--|--|--|--|--|--|------|
| 1881-85, | | | | | | | 9.5 |
| 1886-90, | | | | | | | 8.4 |
| 1891-95, | | | | | | | 6.4 |

The term "diphtheria" does not appear in the records of deaths until 1858, in which year 18 deaths were registered from this cause. There were 32 in 1859, 258 in 1860, increasing rapidly to 1,420 in 1863, and then decreasing until there were less than 300 in each of the six years 1867–72. It then increased rapidly until 1876 and 1877, when it became seriously epidemic in many parts of the State, the deaths from this cause in the two years amounting to 5,244.

While the disease did not appear under the name of diphtheria in the two previous centuries in Massachusetts it is believed that it often prevailed to a serious extent, so far as the limited descriptions of early medical practitioners may be trusted.

Sex. — The death-rate of males from these combined causes was 7.46 per 10,000 and that of females 6.90 in the first period, or in the ratio of 108 males to 100 females in equal numbers living. In the second period the death-rates were 9.94 for males and 9.36 for females, or 106 males to 100 females in equal numbers living.

If the deaths from the two causes are separated, it appears that the death-rate of males from diphtheria in the first period was slightly less than that of females, while the death-rate of males from croup considerably exceeded that of females. In the second period the death-rate of males was higher both from diphtheria and croup.

Seasonal Prevalence. — The monthly mortality from these two diseases exhibits a striking similarity, both when the two diseases are compared and for the two twenty-year periods. The greatest prevalence in each period and in each disease occurred in the months of November and December, and the least usually in July and August, but the table for diphtheria in the period 1856–75 shows a slightly lower figure in May and June.

During the last two years the demands for antitoxin and for the examination of throat cultures received at the office of the State Board of Health from local boards furnish quite a reliable index of the seasonal prevalence of this disease, or group of diseases, as well as the returns furnished under the act relating to the notification of diseases.

Age. — The death-rate * at the age period 0-5 is much the highest, rapidly diminishing to the later ages of life. Considering the two causes separately the difference in mortality between the early ages is much greater in the case of croup than it is in diphtheria. The following figures from the twenty-sixth annual report show that the highest death-rate from diphtheria occurred in the third year of life and that of croup occurred in the second year, though the difference in the latter case between the mortality of the second and third years was slight.

The figures for each year were as follows: -

| | | | Diphtheria. | Croup. | | | Diphtheria. | Croup. |
|---|---|---|----------------------|----------------------|--------------------------|--|--------------|-------------|
| 0-1 years,. 1-2 years,. 2-3 years,. | • | : | 12.4 32.3 38.7 | 13.2 19.5 19.2 | 3-4 years, 4-5 years, | | 37.8 32.9 | 13.5 9.2 |

Table 54. — Death-rate per 10,000 at Early Ages (1887-93).

For a full discussion of the mortality from diphtheria during the period 1871-80 see summary by Dr. C. F. Folsom in thirty-ninth Massachusetts registration report, 1880, pages 80-110.

^{*} See note on page 774.

Typhoid Fever.

Total deaths, 1856-95, 40,029.

The deaths from typhoid fever in 1895 were 680, and this number was, with the exception of the deaths in 1878 and 1879, the least number registered from this cause in the forty years 1856-95. The death-rate in 1895 from this cause was 2.7 per 10,000, this being the lowest death-rate on record for the whole State during the forty-year period, the highest having been 13.4 in 1865. From 1872 down to 1895 the decrease in the death-rate from typhoid fever has been comparatively uniform, the chief exceptions being the years 1880 and 1881, when the death-rate from this cause rose from 3.6 per 10,000 to 4.9 and 5.9.

The total deaths from this cause in the first twenty-year period were 23,265 and the death-rate was 8.6 per 10,000; while those of the second twenty years were 16,764 and the death-rate was 4.1 per 10,000.

It is interesting to note the decline in the typhoid fever death-rate in its general coincidence with the introduction of public water supplies throughout the State, a fact which is shown in the accompanying table and diagram.

Table 55.— Table showing the Proportion of the Population of the State of Massachusetts living in Cities and Towns having Public Water Supplies.

Summary by Decades, 1856-95.

| Period. | Death-rate from Typhoid Fever per 100,000. | Percentage of Population not Supplied with Public Water. | Pi | ERIOI |). | | Death-rate from Typhoid Fever per 100,000. | Percentage of Population not Supplied with Public Water. |
|----------|---|--|----------|-------|----|---|---|--|
| 1856-65, | 92.9 | 75.44 | 1876-85, | | | | 47.4 | 31.75 |
| 1866-75, | 80.8 | 58.94 | 1886-95, | | | ٠ | 36.4 | 13.93 |

The death-rate from this cause has generally fallen as the per cent. of the population supplied with public water has risen, for the reason that the majority of the deaths from typhoid fever have occurred among communities and portions of communities not supplied with public water. Hence, in the foregoing diagram, this percentage of the population (not supplied with public water) is compared with the death-rate from typhoid fever. The method of representation (by ten-year periods) presents a much more uniform showing than that by single years.

In 1856 there were only 11 cities and towns supplied with public water, and the population thus supplied in that year was only 23.2 per cent. of the total population. (In 1850 it was only 19.7 per cent.) In 1870 this percentage had only increased to 35.6, but during the succeeding decade the percentage thus supplied had nearly doubled, being 65.8 in 1880. From that time onward the increase has been quite uniform but less rapid, and amounted in 1896 to 90.1 per cent. of the total population.

It will be seen by the diagram and table that the decrease in the typhoid death-rate from the mean of the decade 1865-75 to the

mean of the decade 1876-85 was also considerably more rapid than that of either the preceding or the succeeding periods.

The death-rates by five-year periods were as follows: 8.0, 10.5, 8.0, 8.2, 4.5, 5.0, 4.1, 3.2.

Seasonal Prevalence. — The two tables indicating seasonal prevalence (pages 769 and 771) show in each a uniform course below the yearly mean from January to July, then increasing rapidly to October in the first period and to September in the second, and then diminishing with nearly the same rapidity to January.

Sex. — The death-rate of males was in each period considerably greater than that of females, the rates in the first period being 9.4 for males and 7.9 for females, or in the ratio of 119 males to each 100 females in equal numbers living, and in the second period 4.6 for males and 3.7 for females, or as 125 males to 100 females.

Ages. — The highest death-rate in the first period appears to have occurred at ages from fifteen to thirty years and among all persons over sixty, those of ages above seventy considerably exceeding all others. In the second period the death-rate at ages fifteen to thirty is greatest but is nearly equalled by that of ages over seventy years. The greatest improvement, comparing the same ages in the two twenty-year periods, appears to have taken place at all ages over fifty years. (Further information relative to the mortality from typhoid fever in Massachusetts may be found in the second report of the State Board of Health, 1871, in a paper by Dr. George Derby.)

Dysentery.

Total deaths, 1856-95, 20,112.

In 1895 the deaths from dysentery numbered 209, and with the exception of those in 1892, which were 193, were the least in number during the whole forty-year period. The death-rate from this cause was only .8 per 10,000 living.

The total number of deaths registered from this cause in the forty years was 20,112, of which 13,786 occurred in the first half and 6,326 in the last half of the period, and the death-rates were respectively 5.1 and 1.6.

The decline in the death-rate from this disease is continuous and well marked. The deaths from this cause in the ten years ending with 1866 were 8,351, while those in the ten years ending with 1895 were only 2,359, the population, meanwhile, having doubled. The

deaths from this cause in the latter period as compared with those in the former were approximately in the ratio of 100 to 658, in equal numbers living. In those early years of the first period, as many practitioners will remember, dysentery was an epidemic disease of the summer months, prevailing to a greater or less degree in almost every city and town in the State, great and small, but within the past twenty years it appears to have very largely lost its epidemic character, its incidence upon the population being comparatively small. Its continuous and comparatively uniform decline points to its possible extinction at no distant period as a factor in the death-rate.

Seasonal Prevalence. — The monthly distribution of dysentery shows that its mortality by months was nearly identical in the two twenty-year periods, remaining at a low figure for the first five months and then rising slightly in June, and then very rapidly to a climax in August, and descending in like manner to November. (See pages 769 and 771.)

Sex. — The death-rate of males in the first period was 5.3 and that of females 4.9, or as 108 deaths of males to 100 deaths of females in equal numbers living. In the second period the conditions were reversed, the deaths of males being 1.49 and that of females 1.63, or in the ratio of 100 males to 109 females in equal numbers living. (See pages 769 and 771.)

Ages. — The death-rate was in both periods highest at the extreme ages of life, that of old age (80+) being the highest in both periods. The greatest relative improvement appears to have taken place at the age periods 0 to 5 and 5 to 10.

Cholera Infantum.

Total deaths, 1856-95, 72,191.

In the following summary are included only those deaths which were registered as from cholera infantum. The addition of all deaths from diarrheal diseases of infants under one year, including those from enteritis, would increase the number by from 25 to 30 per cent.

The deaths from cholera infantum in 1895 were 2,377, and the death-rate 9.5 per 10,000 of the living population.

The total number of deaths from this cause in the forty years ending with 1895 was 72,191, of which 28,893 occurred in the first period and 43,278 in the second. The death-rates from this cause in the two periods were nearly equal, being in the ratio of 10.71 per 10,000 in the first period and 10.66 in the second.

The death-rates of the successive five-year periods were as follows: 6.4, 9.1, 10.1, 15.8, 10.5, 10.5, 10.3, 11.2.

Seasonal Prevalence. — The seasonal mortality of this disease follows very nearly in the same track with dysentery, but with greater departures from the mean annual mortality, the deaths during the eight months from November to June inclusive amounting to less than 7 per cent. of the number for the whole year.

Sex.—The death-rates of the sexes were as follows for the two periods. In the first the death-rate of boys was 11.8 and that of girls 9.7 per 10,000 living, and in the second period 11.8 and 9.6 respectively, or as 100 deaths of girls to 122 of boys in the first and as 100 deaths of girls to 123 of boys in the second period in equal numbers living. (See pages 769 and 771.)

Ages. — The deaths being almost entirely in the first age period of life (0-5) years), a greater difference appears here than in the general death-rate, since the birth-rate, which largely influences the numbers living at the first age (0-5), was considerably greater in the first period than in the second, the death-rate of children under five from cholera infantum being 98 per 10,000 in the first and 115.6 in the second period.

Diarrhœal Diseases.

Total number of deaths in this group, 1856-95, 131,387.

Under this title are included the deaths from cholera infantum, dysentery, diarrhœa, cholera morbus and enteritis.

Two of the principal factors in this group, cholera infantum and dysentery, have already been considered.

The total number of deaths from this group in each twenty-year period with the death-rates were as follows:—

| TABLE | 56. — Deaths | from | Diarrhlpha al | Diseases, | 1856-95. |
|-------|--------------|------|---------------|-----------|----------|
|-------|--------------|------|---------------|-----------|----------|

| | | | DEA | THS. | | | | DEATI | H-RATES | PER 10, | 000. | |
|--------------|----------------------|------------|-----------|--------------------|------------|---------|----------------------|------------|-----------|--------------------|------------|--------|
| Period. | Cholera Infantum. | Dysentery. | Diarrhœa. | Cholera Morbus. | Enteritis. | Total. | Cholera Infantum. | Dysentery. | Diarrhœa. | Cholera Morbus. | Enteritis. | Total. |
| 1856-75, | 28,893 | 13,786 | 6,934 | 1,891 | 5,422 | 56,926 | 10.71 | 5.11 | 2.57 | .70 | 2.01 | 21.11 |
| 1876-95, | 43,278 | 6,326 | 9,971 | 1,756 | 13,130 | 74,461 | 10.66 | 1.55 | 2.46 | .43 | 3.23 | 18.34 |
| Aggregates,. | 72,171 | 20,112 | 16,905 | 3,647 | 18,552 | 131,387 | 10.69 | 2.98 | 2.50 | .54 | 2.74 | 19.45 |

There was, therefore (comparing the two periods), a slight decrease in the death-rate from cholera infantum, a very great decrease in that of dysentery (5.11 to 1.55), a slight decrease in that of diarrhœa (2.57 to 2.46), a considerable decrease in that of cholera morbus (0.70 to 0.43), and a marked increase in that of enteritis (2.01 to 3.23). There was, therefore, a gain, comparing the two twenty-year periods, of 2.77 per 10,000 of the population in the total of these diseases.

Whooping-cough.

Total deaths, 1856-95, 11,586.

The deaths from whooping-cough in 1895 were 269, and the death-rate per 10,000 was 1.1. During the years 1892 and 1893 it was also 1.1, and 1.8 in 1894.

The deaths from this cause in the whole forty-year period were 11,586, of which 6,014 occurred in the first twenty years and 5,572 in the last twenty years, the death-rates of the two periods being 2.2 for the first and 1.4 for the second. The maximum and minimum years of prevalence were 1861, with a death-rate of 3.3 in the first period, and 1883, with 0.7 in the second.

Ages.—In the twenty-sixth report, page xc, it was shown that while measles, scarlet-fever, diphtheria and croup are most destructive to life in the second and third years, whooping-cough destroys greater numbers in the first year of life, the death-rate at that age being nearly three times as great as during the second year. The death-rates for the first ten years (corrected) were as follows:—

| | YE | ARS. | | Death-rate from Whooping-cough. | | YE | ARS. | | Death-rate from Whooping-cough. |
|--------|----|------|--|---------------------------------------|--------|----|------|--|---------------------------------------|
| 0-1, . | | | | 33.7 | 3-4, . | | | | 3.0 |
| 1-2, . | | | | 12.7 | 4-5, . | | | | 1.4 |
| 2-3, . | | | | 5.1 | 5-10, | | | | 0.4 |
| | | | | | | | | | |

Consumption.*

Total deaths, 1856-95, 209,115.

In the report of the Board for 1894 (page lxxv) consumption was treated with greater fulness of detail than other diseases, in conse-

^{*} In this summary the term "consumption" refers only to phthisis pulmonalis, or consumption of the Lungs, except where otherwise stated.

quence, mainly, of the manifest interest in the subject everywhere prevailing. The demand for such information continues, and hence a more minute analysis of the statistics of the mortality from this cause will be presented in this summary. The recent publication by the Board of Dr. Russell's pamphlet on "The Prevention of Tuberculosis" has also increased the public interest in all that pertains to the question.

The number of deaths registered as from consumption in 1895 was 5,486, and the death-rate was 21.9 per 10,000, being the lowest death-rate from this cause yet recorded for the State.

The whole number of deaths registered from consumption in the forty years 1856-95 was 209,115, and the mean death-rate of the whole period from this cause was 30.9 per 10,000 living.

Of the whole number of deaths, 96,278 occurred in the first twenty years and 112,837 in the last twenty, the mean death-rate of each period being, respectively, 35.7 and 27.8 per 10,000. The maximum death-rate in any year from this cause was that of the first year, 1856, and was 40.8 per 10,000, and the minimum (21.9) was that of the last year, 1895, so that the death-rate from consumption had declined nearly one-half in the whole period of forty years.

Sex. — The deaths of males from consumption were 43,314 in the first period and 51,819 in the second, and those of females were 52,941 in the first and 61,016 in the second. The number of persons whose sex was not stated, in the whole period of forty years, was only 25.

The death-rate of males was 33.4 per 10,000 living in the first period and 26.4 in the second, while that of females was 37.8 in the first and 29.1 in the second, thus showing a greater improvement among females than among males.

In the table on page 787 are given the death-rates per million living of each sex by single years for a still longer period (1851–95), and also a comparison of the male and female rates, the former being taken as 1,000, by which it appears that for the ten-year period 1851 to 1860 the mean death-rate of females from consumption to that of males was as 1,296 to 1,000, in the next decade (1861 to 1870) as 1,095 to 1,000, in the third as 1,154 to 1,000, in the fourth as 1,094 to 1,000, and for the single years 1891, 1892, 1893, 1894 and 1895, as 1,074, 1,067, 1,043, 1,020 and 974 females, respectively, to 1,000 males, the female death-rate from this cause being less than that of males for the first time in 1895.

Table 57 .- Phthisis. Annual Death-rates among Persons, Males and Females, in Each Million Living, Massachusetts, 1851-95.

| | | | YEAR. | | | | Persons. | Male. | Female. | Female Rate to Male Rate taken as 1,000. |

In the diagram on this page the same figures are illustrated and show the wide divergence in the death-rate of the sexes in the early

years of the half-century, and their rapid approach up to 1863, from which date the death-rates continue nearly parallel until 1891, when

they again approach rapidly and the male death-rate becomes the greater in 1895.

The diagram also illustrates the figures for England* in similar manner, and shows, first, that in every year the consumption deathrate of England was less than that of Massachusetts, and secondly, that the death-rate of females was at first greater than that of males, but became less in 1866, a much earlier date than that of Massachusetts for the same occurrence.

Seasons of the Year. — In tables 48-51 it appears that consumption has proved fatal in Massachusetts with considerable uniformity throughout the year, the greatest and least mortality from this cause (upon a daily standard of 100) being in March (106.4) and in June (92.2) in the first period, and in April (110.4) and July (93.7) in the second period. The uniformity of its seasonal mortality is therefore greater than that of any of the other diseases enumerated.

Ages. — The highest death-rate from consumption in the first period was at the age period 70 to 80, when it was 87.6 per 10,000 living; that of the age period 20 to 30 was 51.7, and consequently the disease at this age proved fatal to much larger numbers, since the persons living were much greater in number at that age. The lowest death-rate was at ages 5 to 10 and 10 to 15 (page 769).

In the second period (1876–95) the highest death-rate was at ages 20 to 30, and the lowest at ages 5 to 10 and 10 to 15 (page 771).

The greatest improvement, comparing the two twenty-year periods, was at ages 60 and over, the death-rate at these ages in the second period being less than half that of the first period at the same ages. (More definite details relating to the mortality from consumption by sexes and ages will be given in the section entitled "Consumption in its Relation to the Wage-earning Period of Life.")

4 Citles having over 30,000 inhabitants in each. 7 Deaths of persons of unknown ages are included in this group. 8 The figures for Denmark are from "Denmark, its Medical Organization, Hygiene and Demography." Copenhagen, 1891. 3 65 and over.

The greater part of the figures in this table (Table 61) are from a circular of the Imperial Board of Health of Germany, upon the establishment of hospitals for consumptives, published at Berlin, 1896.

This high death-rate of infants under one year in Massachusetts (see column for infants under one year, in foregoing table) is the result of including all deaths certified as deaths from tabes mesenterica, which constitutes over 70 per cent. of the deaths embraced in this group. The rejection of these reduces this ratio (117.3) to 33.6, and makes it comparable with others in the same column, and especially with those of England.

The figures for older ages are affected but little by including tabes mesenterica, since most of the certified deaths from this cause occur in the first year of life.

Consumption in its Relation to the Wage-earning Period of Life.

The question of the prevention of tuberculosis has assumed so much importance in recent years as to make it necessary to present the vital statistics of this cause of death in such form as will be useful for consultation in the most practical manner possible. The disease, unfortunately, affects a very large proportion of the population. It seriously impairs their usefulness, and this, too, at a period of life when the capacity to earn a living is at its maximum.

The highest death-rate from consumption at any age of life is that which prevails at the age period twenty to thirty, although in the earlier years of the last half-century the death-rate from this disease was slightly greater at the age period seventy to eighty. For the twenty-five years 1863–87 the death-rate from this cause at the age period twenty to thirty was 49.4 per 10,000 of the living at that age, and 62.1 of the living at ages seventy to eighty. (See forty-sixth registration report, 1887, page 361.) This excess at advanced ages has disappeared in recent years.

For the purpose of ascertaining the changes which have taken place during the forty-year period 1856-95 we have here presented the deaths from consumption during the first two and the last two years of the period at certain specified ages, and also the deaths from all tubercular diseases, in separate lines. (See tables 57-60.) The diseases embraced in this enumeration are phthisis, or pulmonary tuberculosis, hydrocephalus, tabes mesenterica and scrofula. To these are added the few deaths certified as due to lumbar abscess, cellulitis and goitre, in all amounting to a fraction only of 1 per cent. of the total of tubercular deaths.

The periods of life selected for comparison are three in number, namely, all under fifteen years, fifteen to sixty, and all over sixty years, and in each case the deaths of each sex are also given separately.

For the two years 1894-95 the age period, all under fifteen, is also divided into two periods, all under one year and those from one to fifteen years of age. This was not possible for the years 1856-57, without an undue amount of laborious research, since the deaths under one from different causes were not separately published until 1887, when they were introduced into the registration reports by request of the State Board of Health. Hence an additional short table has been added at the bottom (1894-95, 0-5, 5-15 years) in order to make the figures of the latter period comparable with those of the former.

The principal value of these tables consists in the presentation which they set forth of the relation of consumption to the productive or wage-earning period of life. It is at this time of life that consumption proves by far the most destructive, and that, too, in the earlier part of the period, when the wage-earning capacity is at its maximum.

The method of presentation, the comparison of the number of deaths from this cause with the total number of deaths from all causes, is, we are aware, faulty and open to certain objections, hence we have also presented the same deaths in comparison with the living population at the same ages of life. (See Table 60, page 793.)

The former method was selected in this case and given greater prominence in order to bring out, in the most striking manner, the excessive destructiveness of this disease upon persons of certain ages at the time when their usefulness as wage-earners is at its maximum, and secondly, in order to be enabled to compare the statistics of this character with those of other countries recently published. These figures are presented by the Imperial Board of Health of Germany in a recent circular upon the "Advantages of Institutions for the Treatment of Lung Diseases."*

Percentage of Deaths from Tuberculosis (in General) to Deaths from All Causes in Different Populations at the Wage-earning Period of Life (15-60 Years).

^{*} Ein Beitrag zur Beurtheilung des Nutzens von Heilstätten für Lungen Kranke. Berlin, 1896.

By these tables (page 790) it appears that in every 1,000 deaths from all causes among persons from fifteen to sixty years of age, in the two years 1856 and 1857, 469 were from tuberculosis in general; those of males were 416 and those of females were 516,—in the latter case constituting more than half the deaths from all causes at that period of life. In 1894 and 1895 these figures were reduced to 288 for both sexes, or to 277 in males and 299 in females. In the accompanying diagram for different populations the open squares represent the deaths from all causes and the shaded portions the percentage of deaths from tuberculosis in general.

Percentages of Deaths from Consumption and Other Tubercular Diseases to Total Deaths at Each of Three Periods of Life (under 15, 15-60 and over 60), in 1856-57 and 1894-95, Massachusetts.

It also appears that in every 1,000 deaths from all causes among persons from fifteen to sixty years of age in the two years 1856 and 1857, 462 were from phthisis or consumption of the lungs. Those of males were 409 and those of females 509, in the latter case being more than half the deaths from all causes. In the two years 1894 and 1895 these figures were reduced to 269 for males and 287 for females. (See Table 57, page 790.)

In the age period of life twenty to thirty the mortality was still greater, being, in the two years 1856 and 1857, 482 for males and

579, out of each 1,000 deaths of females. The figures for this age period had also fallen to 398 and 450, respectively, for the two years 1894 and 1895. (See Table 58, page 791.)

These tables also show that the excess of female mortality from consumption among persons over sixty years of age, in the two years 1856 and 1857, had disappeared in the two years 1894 and 1895, and given place to an excess of such mortality among males. They also show the rate of mortality from other tuberculous diseases (not pulmonary phthisis) among children under five years of age.

In Table 60 the deaths and death-rates from consumption and from all tubercular diseases at each of the three periods of life, all under fifteen, fifteen to sixty and all over sixty, are presented for the two periods 1856–57 and 1894–95, and show a marked improvement in the death-rate from pulmonary phthisis at each of these age periods, especially in childhood and old age. The same figures are presented for phthisis in the accompanying diagram.

Comparative Mortality of Males and Females from Consumption at Three Periods of Life (under 15, 15-60 and over 60) in 1856-57 and 1894-95, Massachusetts.

Pneumonia.

Total deaths, 1856-95, 101,226.

The deaths registered from pneumonia in 1895 were 4,652, and the death-rate 18.6. This was higher than that of 1894, but considerably less than those of 1892 and 1893. The death-rates of these three years, 1892, 1893 and 1894, were, respectively, 21.5, 23.0 and 16.8.

The course of pneumonia shows a marked contrast to that of the

majority of infectious diseases, in that it has risen from a death-rate of 8.5 in 1856 to one of 23.0 in 1893. The increase of pneumonia, however, has been marked by greater irregularities than are presented by the decline of consumption.

The total deaths from this cause in the first period were 32,868, and those of the last period were 68,358, making an aggregate of 101,226 in the forty years ending with 1895. The death-rate of the first period was 12.2 per 10,000 and that of the latter was 16.8. The death-rates of the five-year periods were respectively as follows, from 1856 to 1895: 9.6, 11.9, 11.8, 14.7, 14.2, 16.0, 16.4, 19.7.

In a paper read by Dr. C. F. Folsom at the meeting of the American Association of Physicians in Washington, May 1, 1896, the author presents a diagram showing the death-rate from pneumonia in England and in Glasgow from 1852 to 1894. It is therein shown that pneumonia in Glasgow has followed a course in its death-rate very similar to that of Massachusetts, especially since 1858, while in England the death-rate from this cause has diminished down to 1890, when it again increased.

Seasonal Prevalence. — The seasonal mortality of pneumonia indicates a comparatively uniform course throughout the forty years and for the eleven months from February to December inclusive; but the relative death-rate of January appears to be considerably greater in the second period than in the first, probably in consequence of the unusual prevalence of epidemic influenza in the winter of 1889-90 and the three following years. (See forty-ninth registration report, 1890, page 347, and twenty-first annual report of State Board of Health, page 307.)

The greatest maximum departure from the mean annual death-rate from this cause was in March in the first period and in January in the second, and the greatest minimum departure was in August in each period.

Sex. — There was in each period a greater death-rate of males than of females, but the difference was greater in the first period than in the second, the ratio being as 117 males to each 100 females in equal numbers living in the first period, and as 110 males to each 100 females in the second.

Age. — The death-rate appears to have increased at each age of life, but the greatest relative increase occurred at all ages above twenty years. The death-rates at different ages bore nearly the same relative proportion to each other in each period. For example,

the death-rate of age 5 to 10 and age 10 to 15 in the first period were respectively 8.6 and 3.7 per cent. of the death-rate at age 0 to 5, while in the second period they were 9.1 and 3.8 per cent. of the death-rate at that age. At older ages the differences were greater.

Kidney Diseases.

Total deaths, 1856-95, 26,219.

The whole number of deaths ascribed to this cause in 1895 was 1,860, and the death-rate 7.4 per 10,000 of the population. Under this head are embraced all deaths included in the registration reports under the titles "diseases of the kidneys," "nephritis," "nephria" and "Bright's disease." At the suggestion of the State Board of Health the obsolete term "nephria" was stricken from the list after 1887.

The total deaths from this group of causes registered during the forty years were 26,219, of which 4,062 occurred in the first twenty years and 22,157 in the last twenty years. The death-rate of the first period was 1.5 per 10,000 and that of the second was 5.5. The rapid and comparatively uniform increase in the death-rate is remarkable, the minimum death-rate being that of the first three years (1856-58), or .4, and the maximum, 7.4, was that of 1895, the last year of the period.

Sex. — Reference to Table 123 of the forty-sixth registration report (1887) shows that the death-rate of males was generally greater than that of females. In a ten-year period (1878-87) there were 5,291 deaths of males and 3,720 of females from kidney diseases.

Since the diagnosis of diseases of the kidneys has progressed rapidly during the forty years embraced in this period, it is fair to infer that a considerable part of the increase may be due to the transfer to this title of cases which would in earlier times have been referred either to the title of "dropsy," or to that of unknown causes. (See table on page 356 of registration report of 1890, in which it appears that deaths certified as due to kidney diseases had increased more than twentyfold in the forty years 1851–90, while the death-rate ascribed to dropsy in the last years of the period had fallen to less than one-fifth of that which is shown in the first ten years of the period. The result of these changes is shown in the sum of the deaths ascribed to kidney diseases and dropsy, wherein the actual increase in the death-rate from these combined causes is only 50 per cent. for the whole period.)

Heart Diseases.

Total deaths, 1856-95, 67,989.

The whole number of deaths registered as due to heart diseases in 1895 was 3,566, and the death-rate was 14.3 per 10,000. This death-rate was slightly higher than that of 1894 from the same cause, but was less than that of any previous year since 1887.

The total mortality from heart diseases in the forty-year period was 67,989, of which 17,550 occurred in the first half and 50,439 in the last half, the death-rates being respectively 6.5 and 12.4. The minimum death-rate from this cause was 4.9, which occurred in each of the years 1858 and 1859, and the maximum was 16.0, in 1892.

Sex. — Reference to Table 125, registration report of 1890, shows that the death-rate of males from heart disease was slightly greater in number than that of females.

Ages. — In Table 126 of the same report are presented the deathrates from heart disease by ages. From these we have selected the column for 1855, and have added the figures for 1895, these being very nearly the extreme years of the forty-year period under consideration.

By this table it appears that the death-rate has increased at each age period, but the increase has been much the greatest at advanced ages. A comparison of the table referred to with the following table shows that the death-rate at each age in 1890 was greater than that of 1895 at corresponding ages.

The increasing use of the indefinite term "heart failure," as affecting the statistics of this group of causes, has received sufficient comment in the forty-ninth registration report, Massachusetts, 1890 (page 363).

Table 62.— Death-rates by Ages, 1855 and 1895, per 10,000 Living at Each Age.

| | | AGES | | 1855. | 1895. | | 4 | AGES. | | | 1855. | 1895. |

| 20, | • | | | 2.0 | 3.2 | 80, | ٠ | | | | 36.8 | 186.4 |
| 80, | | | | 2.8 | 6.0 | | | | | - | | |

Brain Diseases.

Total deaths, 1856-95, 114,036.

The diseases embraced under this group are those which are included in the registration reports under the titles "apoplexy," "paralysis," "insanity," softening of the brain," and the general terms "cephalitis" and "unspecified diseases of the brain." The unsatisfactory term "cephalitis" has been employed for many years in the registration reports as a makeshift, to include all inflammatory and other diseases of the brain which it was found difficult to place under other titles.

The number of deaths from this group of causes in 1895 was 5,062 and the death-rate 20.2, which was less than that of any year since 1890.

The whole number of deaths in the forty years from brain diseases was 114,036, of which 36,054 occurred in the first half and 77,982 in the last half of the period. The death-rate of the first half was 13.4 and that of the last half 19.2, or not quite 50 per cent. greater. That of the minimum year (1856) was 9.4, and that of the maximum years (1892 and 1893) was 21.5 per 10,000.

Cancer.

Total deaths, 1856-95, 31,140.

The deaths registered as from cancer in 1895 were 1,749. This was a much larger number than that of any previous year. The death-rate was 7.0 per 10,000, as compared with 6.4 in 1894. There has been a very steady and comparatively uniform increase in the death-rate from this cause from a minimum of 1.9 in 1856, the first year of the period, to 7.0 in 1895, the last year.

The total number of deaths from cancer in the whole period of forty years was 31,140, of which 8,219 occurred in the first twenty years and 22,921 in the last twenty years. The death-rates of the two periods were respectively 3.0 and 5.6. Those of the five-year periods were as follows: 2.3, 2.7, 3.3, 3.7, 4.5, 5.4, 5.9, 6.4.

In the early registration reports the term "cancer" appears alone, without specification as to its seat or location; the term "cancer of the stomach" first appears in the report of 1867, "epithelioma" in 1876, "cancer of the liver and uterus" in 1878, "of the bowels" in 1881, and of the "breast," "spleen," "kidneys" and "pancreas" in 1887.

If the principal portion of these deaths (those embraced in the term "cancer" without specification as to location) be considered separately, the increase in the death-rate of this portion is found to be comparatively small.

It is plain that the increase in the death-rate from cancer is partially due to more accurate methods of diagnosis. For example, the deaths from cancer in 1876 were 659, of which 565 were from cancer (part not stated), 92 from cancer of the stomach and 2 from epithelioma, while in 1895 the deaths from cancer were 1,749, which were specified as 903 from cancer (part not stated), 201 from cancer of the liver, 1 from cancer of the pancreas, 305 from cancer of the stomach, 193 of the uterus, 108 of the breast, 19 of the kidneys, 2 of the bowels, 2 of the spleen and 14 from epithelioma.

The increase in the deaths registered as cancer simply, without stating its location, during the twenty years 1876-95, was only from 3.4 to 3.6 per 10,000 of the population, while the increase in the deaths from cancer in which the part or organ affected was stated was nearly six-fold, or from .56 to 3.4 per 10,000 living. It is needless to add that the changes due to improved diagnosis would naturally become manifest mainly in this latter class, although a transfer of some deaths from the indefinite to the definite class might also occur.

Sex. — The following table shows the death-rates of the two sexes from cancer for the two twenty-year periods.

The deaths of males in the first period were 2,627 and of females 5,592, and the death-rates 2.02 and 4.00 per 10,000; and in the latter period the deaths were respectively 7,256 and 15,665, and the death-rates 3.70 and 7.47; the increase of males being at the rate of 2.41 per cent. and that of females 2.85 per cent.

Table 63.—Death-rates from Cancer per 10,000 Living, Massachusetts, 1856-95.

| | Males. | Females. | | Males. | Females. | | Males. | Females. | | Males. | Females. |
|-------|--|--|-------|--|--|-------|--|--|---|--|--|
| 1856, | 1.29 1.37 1.70 1.69 1.74 1.67 1.72 1.78 1.86 2.06 | 2.45 2.89 3.12 3.64 3.69 3.34 3.33 3.31 3.83 | 1866, | 1.75 2.12 2.21 2.14 2.61 2.30 2.46 2.62 2.45 2.18 | 4.50 3.70 4.17 4.71 4.41 4.98 4.54 5.07 4.73 4.90 | 1876, | 2.53 2.15 3.12 3.25 3.56 3.85 3.41 3.60 3.83 3.56 | 5.23 5.32 6.10 6.45 6.73 6.47 7.16 7.19 7.15 6.91 | 1886, . 1887, . 1888, . 1889, . 1890, . 1891, . 1892, . 1893, . 1894, . | 3.47 3.60 4.02 3.92 3.81 3.93 4.10 4.32 4.37 4.40 | 7.43 7.68 7.91 8.13 8.45 8.14 7.78 8.38 8.34 9.44 |

The following figures show a similar steady increase in the death-rate from cancer in England and Wales:—

Deaths from Cancer per 10,000 of the Population in England and Wales.*

| 1861-70, 1871-80, 1881-90, | | | | | | | | : | | | | 4 | | 3.9 4.7 5.9 |
|----------------------------------|--|--|--|--|--|--|--|---|--|--|--|---|--|-------------------|
|----------------------------------|--|--|--|--|--|--|--|---|--|--|--|---|--|-------------------|

Child-birth.

Total deaths, 1856-95, 12,075.

But little account has been taken in the registration reports of the changes which have occurred in the mortality from the diseases and incidents of child-birth. Hence a column has been introduced in Table 46 in which these data are presented.

It is desirable to state clearly at the outset what deaths should be included under this title, since several terms are employed, and also what shall be the standard of comparison in stating a death-rate. It was therefore decided to include all deaths classed as from child-birth (under this term are embraced all deaths specified as from abortion, child-birth, miscarriage and puerperal convulsions), puerperal fever, metritis, metria,† puerperal septicæmia, and the excess of female deaths from septicæmia over those of males.

With reference to the standard of comparison these deaths are those of one sex only, and mostly at ages from fifteen to forty-five, hence it seemed best not to employ the living population as a standard, as is done in the other columns of the table, nor should the living births be used as a standard, since still-births subject the mothers to the same puerperal dangers as living births. The standard employed is, therefore, the number of cases of births occurring in each year, obtained by taking the sum of cases of living and of still births.‡ Each case of plural birth is also reckoned as a single case. The relative figures represent deaths per 10,000 cases of birth, and show a considerable decrease comparing the two periods. The whole number of cases of birth in the forty years was 1,820,756, and the deaths by child-birth, etc., 12,075, or 66.3 per 10,000. In the first period (1856-75), with 745,461 cases of birth, there were 5,584 deaths in

^{*} Registrar-General's Decennial Supplement, vol. 1, London, 1895, page 54.

[†] An obsolete term adopted by Dr. Farr.

[‡] This method was adopted in order to make the figures comparable with those of other countries.

child-birth, or 74.9 per 10,000, and in the second period (1876-95) 1,075,295 cases of birth produced 6,491 deaths, or 60.4 per 10,000.

The death-rates by five-year periods were as follows: 68.6, 68.1, 76.2, 83.8, 73.3, 72.9, 54.4, 48.2.

There appears to have been an increase up to the fourth period, and then a greater decrease to the close.

In the following table and diagram are presented the figures for Massachusetts and those of a similar table published by Brennecke for Prussia, in each of which a rise appears during the first half of the period and then a greater fall to the close of the table:—

TABLE 64.

The column of figures for Prussia in this table is taken from a paper by Dr. H. B. Brennecke of Magdeburg, entitled "Errichtung von Heimstätten für Wochnerinnen,"* and extends over a period of fifty years (1844–93). It contains the statistics of 296,867 deaths from child-birth and its incidents out of 44,095,659 cases of labor.

In commenting upon that portion of the foregoing table which relates to the mortality of child-bearing women in Prussia, Brennecke

^{*} Vierteljahrsschrift für öff. Gesundheitspflege, 1897, page 81, vol. 29.

says: "Hegar in 1892, at the gynæcological congress in Bonn, properly called attention to the fact that the sudden and surprising fall of the puerperal mortality curve in 1874 was not due to the influence of antiseptics (which were not employed at that time in the country districts), but may be attributed solely to the fact that in 1874 the administration of the official registration passed out of the hands of the clergy into those of the civil authorities. I have no doubt," says Hegar, "that the collection of the statistics was conducted more accurately by the clergy than by the civil authorities, since in the country districts the clergy are especially well informed as to the condition of the families under their care. They are summoned in cases of child-birth, and know when death in childbed occurs. The civil authorities are not so well informed."

Whether the foregoing comments in regard to the cause of the changes in the death-rate from the incidents of child-birth in Germany are correct is a question. They certainly do not apply to the similar column of statistics for Massachusetts, since while the Massachusetts column shows precisely the same sudden fall three years later, it is not true that any change in the methods or the authorities collecting the statistics have here taken place, since they have from the very outset, in 1842, been collected by the city registrars and the town clerks throughout the State.

Certain Minor Causes of Death.

Cerebro-spinal Meningitis. — This term does not appear as a cause of disease in the published registration returns until 1873, in which year 747 deaths from this cause were registered, a number more than three times as great as that of any succeeding year from the same cause. During the few preceding years all deaths returned as from this cause were classed under the vague and indefinite term "cephalitis."

In the preceding year, 1872, Dr. Derby had called attention to the prevalence of cerebro-spinal meningitis, and had published a brief statement relative to the disease in the registration report of that year.

In the three years 1873, 1874 and 1875, the last years of the first twenty-year period under consideration, 1,159 deaths from this cause were registered, and when compared with the mean population of the three years the death-rate was 2.4 per 10,000 living.

In the second period the disease prevailed more or less in each year, the minimum mortality being 78 deaths in 1878 and the maximum, 171 in 1888, the total for the second period being 2,646, and the mean death-rate 0.65 per 10,000 for the whole period.

Erysipelas. — Total deaths, 1856-95, 7,688. The deaths from erysipelas in the first period were 3,565, and the mean annual death-rate 1.3. Those of the second period were 4,123, and the death-rate 1.0 per 10,000, thus showing a slight improvement, comparing the two periods. The maximum for the whole forty-year period was 262, in 1875, and the minimum 124, in 1862.

Influenza. — Total deaths, 1856-95, 4.315. The whole number of deaths registered as due to influenza in the first period was 943, and the mean annual death-rate per 10,000 from this cause was 0.35. In the second period the deaths were 3,372, and the mean annual death-rate 0.83 per 10,000.

In no year of the first period did the deaths attributed to this cause exceed 92 (1857), and in no year of the second period previous to 1890 did they exceed 48, but in 1890 they suddenly rose from 27 to 411, and in the six closing years of the period they were, respectively, 411, 546, 967, 296, 370 and 457, the deaths from this cause in these six years constituting more than 90 per cent. of all the recorded deaths from the same cause in the twenty-year period 1876-95. (For further information relative to the deaths from other diseases occurring coincident with the outbreaks of influenza, see forty-ninth registration report, 1890, pages 347-351, also a summary of the epidemic of 1889-90 in the twenty-first annual report of the State Board of Health, 1889.)

Malarial Fever. — Total deaths, 1856-95, 1,458. The deaths from malarial fever are those which are registered under the titles "ague" and "remittent fever." In the first period they were 465 in number and in the second 993, the mean annual death-rates being respectively 0.17 and 0.24 per 10,000 living. The highest number in any year was 86, in 1893, and the lowest 8, in 1859. During the years 1863-64 (the midst of the civil war) the numbers were nearly doubled, as compared with the mean annual number of that period.

Since the beginning of its recrudescence in Massachusetts in the second period the deaths from this cause have also notably increased, but, in consequence of its comparatively mild fatality, the death-rate from this cause has at no time been high. (For further information

relative to its prevalence, see reports of the Board for 1880, 1885 and 1889, also the second joint report of the State Board of Health and the Metropolitan Park Commission, 1895.)

Rheumatism. — Total deaths, 1856-95, 6,516. The deaths registered as from rheumatism in the first period were 2,329 and in the second 4,187, and the mean annual death-rates were respectively 0.86 and 1.03 per 10,000 living, thus showing a slight increase. The death-rate maintained a fairly uniform course, with a slight tendency to increase throughout the whole period.

Hydrophobia. — This disease appears occasionally as a spasmodic epidemic lasting for one or more years, but never proving very destructive to life. The following statistics are for the entire period of registration, ending with 1895.

There were no deaths registered from this cause in 1895 nor in 1894.

The number registered in the whole period of registration was 117. The number of deaths in each year was as follows:—

Table 65. — Deaths from Hydrophobia, Massachusetts, 1842-95.

| 1842-47 | , . | | | | | 0 | 1873, | | | | | | (|
|---------|-----|---|---|----|---|-------|-------|-----|---|--|---|---|-----|

| 1871, | | | | | | 0 | Tot | al, | | | | | 117 |
| 1872, | | | | | | 0 | | | | | | | |

The average number of deaths in each year from hydrophobia was but little more than 2, and in twenty-seven years, or just half the whole number of years (see foregoing table), there were no deaths from this cause. The two principal epidemics were those of 1876–81 and 1888–91.

Sex. — The deaths of males were 96, or 82 per cent., and the females were 21, or 18 per cent., of the whole number of deaths from this cause.

Ages. — The deaths by ages were as follows: —

| 0-5, | | | | 13 | 40-50, | | • | • | • | 9 |
|--------|---|---|---|----|----------|----|---|---|---|----|
| 5-10, | | | | 25 | 50-60, | | | | | 10 |
| 10-15, | | | | 14 | 60-70, | | | • | | 6 |
| 15-20, | | | | 10 | 70-80, | | | | • | 2 |
| | | | | | Over 80, | | | | | |
| 30-40, | • | • | • | 14 | Unknown | ı, | • | • | | 1 |

By this table it appears that over 44 per cent. of the victims of this disease were children under fifteen years of age.*

Prevalence by Months. — The deaths by months were as follows:—

| January, | | | 8 | July, . | | | 6 |
|-----------|--|--|----|------------|--|--|----|
| February, | | | 9 | August, | | | 15 |
| March, | | | 10 | September, | | | 9 |
| April, . | | | 10 | October, | | | 13 |
| May, . | | | 10 | November, | | | 8 |
| June, . | | | 10 | December, | | | 9 |

This table shows a fairly uniform distribution throughout the year, with the greatest number in August and the least in July.

Counties. — The distribution of the deaths by counties was as follows: —

| Barnstable, | | | 2 | Middlesex, | | | 27 |
|-------------|--|--|----|------------|---|--|-----|
| Berkshire, | | | 3 | Nantucket, | | | 0 |
| Bristol, | | | 14 | Norfolk, | • | | 16 |
| Dukes, . | | | 1 | Plymouth, | | | 3 |
| Essex, . | | | 18 | Suffolk, | | | 14 |
| Franklin, | | | | Worcester, | | | 7 |
| Hampden, | | | 7 | | | | |
| Hampshire, | | | 2 | Total, | | | 117 |

In those communities where dogs are constantly muzzled, as in Berlin, hydrophobia has been practically "stamped out." (Further

^{*} Out of 960 deaths from this cause in England from 1854 to 1888, 51 per cent. were among persons under twenty years of age.

information relative to this disease may be found in the twenty-second report of the Board, 1890, page xxvii.)

Comparing the two twenty-year periods 1856-75 and 1876-95 the deaths from hydrophobia in the former were 13 and in the latter 89, the death-rates being respectively 0.005 and 0.022 per 10,000 inhabitants, the death-rate having increased more than fourfold. These figures, however, are comparatively insignificant in consequence of their small number.

Glanders. — Total deaths, 1856-95, 23. No deaths were recorded from this cause until 1869, and there were only 9 in the first twenty-year period. In the second period the number of deaths from this cause was 14. It is worthy of note that 4 of these deaths, the greatest number in any one year, occurred in 1872, the chief epidemic year of the forty-year period.

Malignant Pustule. — Total deaths, 1856-95, 104. The whole number of deaths registered from this cause in the first period was 67, and those in the second period were 37, the mean annual death-rate having fallen from 0.025 to 0.009 per 10,000 living. Although the whole number of deaths is small, this decrease in the death-rate is notable. The deaths attributed to this cause occurred for the most part in a few small towns, in which the industries of tanning and of sorting horse-hair were conducted. During the first period attention was drawn to this form of disease and to the necessity of adopting measures for its prevention.

The greatest number of deaths in any one year (9) occurred in 1868 and in the first period, while the greatest number in any year of the second period was 5.

Alcoholism and Syphilis. — A certain number of deaths are certified every year as due to intemperance and syphilis. No summary of the statistics of these causes of death can have actual value as representing the prevalence of alcoholism and venereal diseases for the following reasons:—

Such returns cannot in any sense be regarded as an index of the prevalence of intemperance, since there can be no doubt that the desire to spare the feelings of surviving relatives limits the statement as to this cause of death to those cases where no disguise is possible.

The undue prominence of the cases reported in the more populous counties may be regarded as partly due to the public institutions existing in those counties. (From forty-ninth registration report, 1890, page 362.)

For a full digest of the deaths from violence reported by medical examiners as due directly or indirectly to intemperance in 1888, see forty-seventh registration report, Massachusetts, 1888, pages 399-405.

Fully two-thirds of the deaths credited to syphilis are those of infants under one year of age.

THE BALANCE OF MORTALITY.

The death-rate of Massachusetts has maintained a fairly uniform course throughout the forty years under consideration, comparing long periods of time with each other. That of the first twenty-year period was 19.49 and that of the second 19.51 per 1,000 of the living population. This uniformity was maintained notwithstanding the fact that one of the chief factors, the density of population, had more than doubled during the whole period of forty years. When single years are considered the variation from a mean of about 19.5 per 1,000 was quite apparent, the highest death-rates being 22.83 and 22.85 per 1,000 in 1864 and 1872, and the lowest 17 and 17.33 in 1867 and 1859, or 17.2 per cent. above and 12.8 per cent. below the mean for the two extremes.

The death-rate is composed of a variety of different factors; for example, the deaths of persons of different sexes and ages and persons dying from different causes. While the death-rate has remained nearly uniform, the factors which compose it have varied in a remarkable degree. Certain causes of death or general groups of causes have diminished notably in their incidence upon the population, while others have quite as notably increased. Infectious diseases generally, including consumption, have diminished, while most of the so-called local diseases (those of the nervous, respiratory, circulatory organs, etc.) have increased, and the result has been a balance or a maintenance of uniformity in the general death-rate.

The same facts have been observed in the vital statistics of other countries. (See the Registrar-General's decennial report, England, part 1, page xxiii, supplement to fifty-fifth report, also the paper of Dr. G. B. Longstaff, entitled "The Decline in the Death-rate.")

What the outcome of these changes may be in the future it is impossible to state. Should the marked decrease in the death-rates from consumption, typhoid fever, scarlet-fever and other infectious diseases continue for a series of years, it is plain that this decrease must be limited, since they can only fall to zero, while, on the other

hand, those causes of death which are increasing can continue to rise indefinitely. It is therefore desirable that greater attention should be paid in the future to those causes of death which cause the heaviest loss of life.

The changes here alluded to also affect the death-rates at different ages, since the diminishing causes of death (the infectious diseases) are mainly diseases of childhood and early life, while the increasing causes are chiefly those of advancing age, and the general effect would be the prolonging of the life of the population.

To quote again the words of Dr. Longstaff: "The gain under phthisis is more important than the loss under cancer, kidney diseases, etc., since the lives saved are more valuable than those which are lost."

The following table may be termed a balance-sheet of mortality. It presents the deaths for two successive ten-year periods, 1875-84 and 1885-94, and shows quite conclusively that while the difference in the death-rate of the two periods was comparatively slight, amounting to only 0.2 per 1,000 living, or 212 per million, the factors which contribute to the death-rate have undergone a material change.

Column 1 presents the names of certain diseases and groups of diseases or causes of death; columns 2 and 3 present the numbers of deaths from each cause or group of causes for each of two successive ten-year periods; columns 4 and 5 give the annual death-rate per million of the population from each cause; and columns 6 and 7 give the decrease and increase in the death-rate from each cause, comparing the two periods.

Note. — Allowance must be made for the effect of medical progress and more exact methods of diagnosis upon any series of figures covering a period of twenty years. The general effect is to change as well as improve existing systems of nomenclature and classification, and hence to disturb the significance of figures representing the causes of death during the period in question.

For example, the line entitled "dropsy" might be erased, and the deaths distributed in due proportions, chiefly under the titles "heart diseases," "kidney diseases" and "diseases of the liver," where they undoubtedly belong.

Part of the steady decrease in phthisis may possibly be due to a more accurate distribution of such deaths under pneumonia, developmental diseases, etc.

The general result, however, showing the decrease of infectious and the increase in local diseases, would not be very greatly affected by such distribution.

In the foregoing table the sum of the specific death-rates in columns 4 and 5 constitutes the mean annual death-rate per million from all causes for each ten-year period, namely, 19,491 and 19,703, or as usually read, 19.5 and 19.7 per 1,000 of the living population.

When reckoned in terms of the total mortality the result is the same. In the twenty years 1871-90 the following diseases, measles,

scarlet-fever, diphtheria and croup, typhoid fever and consumption, had diminished in their percentage of the total mortality from 28.4 to 19.7, while pneumonia, apoplexy and paralysis, diseases of the heart and kidneys, had increased in the same time from 17 per cent. of the total mortality to 26.3 per cent.

The effect of this upon the lifetime of the population is best shown by a quotation from a life-table, and for this purpose the following condensed table for English males is given, since it is not practicable to present a similar table for Massachusetts with accuracy, for reasons already stated. The table will answer fairly well for Massachusetts, since similar changes in the factors composing the death-rate are taking place in both communities.

For the sake of brevity the tables for males only are quoted and these only at the decennial periods, at birth, ten, twenty, thirty years, etc.

| English | MAI | ES. | 1838-54. | 1871-80. | 1881-90. | ENGLISH MA | LES. | 1838-54. | 1871-80. | 1881-90 |

| 60 years, | | | 19.54 | 18.93 | 18.82 | | | | | |

Table 67. — Mean After Lifetime, or Expectation of Life (English Males).

These figures show a gain in all ages up to forty (actually to forty-four), comparing the table for 1881-90 with that of 1871-80, and a loss at the later ages of life. The table for females shows similar changes, except that the gain continues up to age forty-four, comparing the column for 1881-90 with each of the preceding tables.

The figures for Massachusetts present similar changes with those of England, so far as can be learned from the more or less crude methods which must necessarily be employed in estimating the mean after lifetime of a fluctuating population.

The following figures are introduced for the two twenty-year periods under consideration in this summary to show the principal factors which have contributed to these changes in the death-rates from different causes during these periods:—

Table 68. — Death-rates from Certain Causes and Groups of Causes, 1856-95, by Five-year Periods.

| | | | | FALL. | | Rise. |
|---|-----|------------|---|---|---|---|
| PERI | ор. | | Causes. | Death-rate per 10,000 from these Causes. | Causes. | Death-rate per 10,000 from these Causes. |
| 1856-60, 1861-65, 1866-70, 1871-75, Mean, | | · } · } | Small-pox, measles, scarlet- fever, diphtheria and croup, typhoid fever, cholera infan- tum, consumption, whooping- cough, dysentery and child- birth. | 93.0 | Pneumonia, kidney diseases, heart dis- eases, brain diseases and cancer. | 27.7 34.7 36.6 44.9 36.6 |
| 1876-80, 1881-85, 1886-90, 1891-95, Mean, | | :} | Small-pox, measles, scarlet- fever, diphtheria and croup, typhoid fever, cholera infan- tum, consumption, whooping- cough, dysentery and child- birth. | 65.1 | Pneumonia, kidney diseases, heart dis- eases, brain diseases and cancer. | 46.8 56.7 62.2 68.8 |

From the foregoing it appears that the deaths from the infectious group diminished from 81.7 (maximum 93) to 50.5 in the forty years, comparing the first five years with the last, and those of the other group of certain local causes and cancer had risen from 27.7 to 68.8 per 10,000.

The mean of the first group in the first twenty years was two and one-third times as great as that of the second group, while in the last twenty years the two means were nearly equal, 60.4 and 59.6.

THE RETURNS OF MEDICAL EXAMINERS.

The deaths returned by the medical examiners embrace all deaths of a violent, sudden, suspicious or doubtful character which have been referred to the medical examiners for investigation, and have been reported officially by them to the Secretary of State.

It has been customary to divide these deaths into four groups, deaths by homicide, suicide, accident or negligence, and such deaths from natural causes as have also been referred to the medical examiner in consequence of their sudden or doubtful character.

In a considerable portion of all these deaths the cause has been decided or confirmed by autopsies.

The law under which such deaths are now investigated was enacted in 1877, and substituted the present medical-examiner system in place of the old coroner's inquest, with its useless adjunct, the coroner's jury. From that time until 1885 there was no legal enactment requiring an official return of such deaths to the State authorities, but by the organization of the Massachusetts Medico-Legal Society a system of voluntary reporting was at once established, and was continued without interruption until 1885, when a law was enacted requiring such returns in all cases.

These first returns, for the period from July 1, 1877, to Dec. 31, 1884, inclusive, are incomplete, and comprise about three-fourths of the deaths of this class which were investigated during that period. From Jan. 1, 1885, onward the returns are complete, and comprise all the deaths of this class. Hence, while in the first period (1877–84) the ratio of deaths of each class to the whole number investigated may be considered as fairly accurate, the comparison with the living population can only fairly be made in the second period (1885–95).

Table 69.— Deaths investigated by Medical Examiners.

|-------|------|---|-------|----|---|---|---|-----------|----------|-------------------------------|--------------------|--------|-----------|
| 1885, | | | | | | | | 45 | 181 | 567 | 485 | 1,278 | 165 |
| 1886, | | | • | • | • | • | • | 47 | 157 | 678 | 496 | 1,378 | 202 |
| 1887, | | | | | | | | 52 | 173 | 748 | 583 | 1,556 | 188 |
| 1888, | | | | | | | | 52 | 190 | 785 | 624 | 1,651 | 219 |
| 1889, | | | | | | | | 51 | 199 | 792 | 612 | 1,654 | 216 |
| 1890, | | | | | | | | 35 | 196 | 862 | 680 | 1,773 | 206 |
| 1891. | | | | | | | | 60 | 187 | 866 | 727 | 1,840 | 225 |
| 1892, | | | | | | | | 72 | 273 | 974 | 890 | 2,209 | 272 |
| 1893, | | | | | | | | 76 | 290 | 976 | 879 | 2,221 | 269 |
| 1894, | | | | | | | | 68 | 270 | 975 | 846 | 2,159 | 272 |
| 1895, | | | | | | | | 74 | 281 | 1,019 | 943 | 2,317 | 271 |
| То | tal, | | | | | | | 632 | 2,397 | 9,242 | 7,765 | 20,036 | 2,505 |

By the foregoing table it appears that during the years in which no official returns were required 7,058 deaths had been reported to the Medico-Legal Society as having been investigated by the medical examiners, of which number 498, or 7.1 per cent., were homicides, 925, or 13.1 per cent., were suicides, and 3,084, or 43.7 per cent., were deaths from accident or negligence. In the second period, when returns were obligatory and presumably complete, the whole number of deaths investigated was 20,036, of which 632, or 3.1 per cent., were homicides, 2,397, or 12.0 per cent., were suicides, and 9,242, or 46.1 per cent., were accidental deaths.

The number of autopsies returned in the first period was 1,500, or 21.3 per cent. of the whole number investigated. In the second period the autopsies were 2,505, or 12.5 per cent. of the number investigated.

In the first period, 1,417 inquests were reported as having been conducted, or 20.1 per cent. of the whole number. The number of inquests was not reported in the second period.

The foregoing figures have but little significance as to the actual ratio or death-rate from these forms of death by violence. Comparing the figures in the second period with the living population it appears that the death-rate from homicide in the eleven years 1885-95 was 0.26 per 10,000 of the living population, a slight increase having taken place, comparing the first years of the period with the last, the minimum being 0.16 in 1890, and the maximum 0.32 in 1893. From suicide* the death-rate was 0.97 per 10,000

^{*} For further statistics upon the subject of suicide, see 46th Mass. Registration Report, 1887.

living, the minimum being 0.78 in 1886, and the maximum 1.21 in 1893. From accident the death-rate was 3.8 per 10,000, the minimum being 2.9 in 1885, and the maximum 4.1 in 1892, 1893 and 1895.

With reference to methods, out of 2,613 suicides in which the method selected was specified, 668 committed suicide by hanging, 463 by drowning, 527 by shooting, 300 by knife-wounds of the neck, and 655 by poison, the chief poisons employed being the different preparations of arsenic and of opium.

Previous to the repeal of the law limiting the percentage of carbonic oxide in illuminating gas, only 6 suicides by the use of illuminating gas had been reported, but in the seven years following the removal of this restriction 62 by this method were reported by medical examiners.

Out of 9,022 deaths by accidental means, 4,179 were railroad accidents, including those which occurred on street railways, the number of which has considerably increased since the introduction of electricity as a motive power. There were 3,169 by drowning, 1,456 by falls, blows and falling bodies, and 218 by poison.

Accidental deaths by inhaling illuminating gas had also increased very largely since the introduction of water gas.

Deaths of infants by overlaying and asphyxia in bed have also materially increased, from 64 in the five years 1886-90 to 145 in the five years 1891-95. These were nearly all infants under one year old.

Suicides.

The following summary of suicidal deaths comprises the statistics of the forty-year period 1856-95.

The whole number of such deaths in the forty years was 5,445, of which 4,271 were males and 1,174 were females. Of this number, 1,919 occurred in the first period and 3,526 in the second. This indicates a slight increase in the death-rate from this cause from 0.71 per 10,000 living annually in the first period to 0.87 in the second period.

Sex. — The increase in men was greater than that among women, that of men in the first period having been 1.14 per 10,000 and in the second 1.42, indicating an increase of 25 per cent., and that of women increasing from 0.32 to 0.35, or 10.4 per cent.

The seasonal intensity of the mortality from suicide is indicated by the following figures:—

| Suicides | by | Months. |
|----------|----|---------|
|----------|----|---------|

| | | | | | Deaths. | Death-rate reduced to a Mean of 100. | | | | | Deaths. | Death-rate reduced to a Mean of 100. |
|-----------|---|---|---|---|---------|---|------------|--|---|---|---------|---|
| January, | | | | | 368 | 80 | July, . | | | ٠ | 510 | 110 |
| February, | ٠ | | | | 325 | 77 | August, | | | | 467 | 101 |
| March, . | | | ٠ | | 463 | 100 | September, | | | | 443 | 99 |
| April, . | | | | | 578 | 129 | October, | | | | 432 | 93 |
| May, . | | | | | 512 | 111 | November, | | | | 416 | 93 |
| June, . | • | • | ٠ | ٠ | 521 | 117 | December, | | • | ٠ | 409 | 89 |

Ages. — The following are the figures for ages, with the annual death-rate per 10,000 living at each age:—

| | AGE | 3, | | Deaths. | Death-rate. | | A | GES | | | Deaths. | Death-rate |
|--------|---------|----|--|---------|-------------|--------|-------|-----|--|---|---------|------------|
| 10-15, | | | | 17 | 0.03 | 50-60, | | | | | 1,010 | 2.00 |
| 15-20, | • | | | 162 | 0.26 | 60-70, | | | | ٠ | 749 | 2.34 |
| 20-30, | | | | 904 | 0.73 | 70-80, | | | | | 392 | 2.58 |
| 30-40, | | | | 1,023 | 1.07 | 80 and | over, | | | | 83 | 1.78 |
| 40-50, | | | | 1,054 | 1.44 | | | | | | | 1 |

Deaths by Lightning.

During the forty years 1856-95, 149 deaths were registered as having been caused by lightning. No deaths were registered as from lightning in 1861, 1864 and 1891. In the other years the deaths from this cause varied from 1 to 10 in each, 10 having been reported in 1892 and 9 in 1872.

Sex. — Of the whole number, 102, or 68.5 per cent., were males and 47, or 31.5 per cent., were females.

Seasons. — The deaths by months were as follows: —

| January | ., . | | | 0 | August, . | | | | | | 50 |
|---------|------|--|--|----|-----------|---|---|---|---|---|------|
| Februar | | | | | 0 | | | | | | 6 |
| March, | | | | | | | | | | | 0 |
| April, | | | | | November, | | | | | | 0 |
| May, | | | | 10 | December, | | | | | | 1 |
| June, | | | | 24 | m . 1 | | | | | _ | 1.10 |
| July, | | | | 53 | Total, | • | • | • | • | • | 149 |

Eighty-five per cent. of the whole number occurred in the three summer months.

Ages. — The deaths by ages were as follows: —

| Unde | r 5 | , . | | | 4 | 50, | | | | 14 |
|------|-----|-----|--|--|----|----------|--|--|---|-----|

VITAL STATISTICS OF CITIES, 1894 AND 1895.

In Table 70 (page 826) are presented the most important items of vital statistics in the cities and large towns having more than 10,000 inhabitants for the two years 1894 and 1895. Of these there were 39 in 1895, having a total population of 1,719,680, or 68.8 per cent. of the population of the State. This urban population may be divided into four groups, as follows:—

| Group I. | One city having a population of more than 100,000, | Population. 496,920 |
|------------|--|----------------------|
| Group II. | Nine cities having populations of more than 50,000 | Total Population. |
| 1 | and less than 100,000 in each, | 627,471 |
| Group III. | Ten cities having more than 25,000 and less than | |
| _ | 50,000 in each, | 308,466 |
| Group IV. | Nineteen cities and towns having more than 10,000 | |
| | and less than 25,000 in each, | 2 86,823 |

In nearly every particular these groups are found to bear a direct relation to the density of population in the different groups.

By groups the principal data were as follows: -

| | | P | ER 1,000 | | | DEAT | TH-RATE | S PER 1 | 0,000 FR | ои — | |
|---------------|--|----------------|-------------|-------------|--------------|------------|-------------------|-----------------------|----------|----------------|----------------------|
| | | Marringe-rate. | Birth-rate. | Death-rate. | Consumption. | Pneumonia. | Typhoid Fever. | Diphtheria and Croup. | Measles. | Scarlet-fever. | Cholera Infuntum. |
| Group I., . | | 23.1 | 31.2 | 23.2 | 31.5 | 24.7 | 3.1 | 15.6 | 0.5 | 3.2 | 10.9 |
| Group II., . | | 18.9 | 29.7 | 19.5 | 20.8 | 17.1 | 3.1+ | 6.2 | 0.6 | 2.9 | 14.8 |
| Group III., . | | 18.1 | 29.0 | 18.0 | 20.1 | 15.2 | 2.4 | 6.8 | 0.5 | 1.6 | 9.5 |
| Group IV., . | | 15.9 | 27.6 | 16.7 | 19.1 | 14.1 | 3.3 | 5.8 | 0.3 | 2.1 | 8.9 |

The cities and large towns having the highest and lowest rates were as follows:—

Marriage-rates (Persons Married), 1894-95. The State = 17.7.

| | | | | Highest. | | | | | | Lowest. |
|--------------|--|--|---|----------|------------|-----|---|--|--|---------|
| Chicopee, . | | | | 27.3 | Woburn, | | | | | 13.9 |
| Boston, | | | | 23.1 | Medford, | | | | | 13.2 |
| Lawrence, . | | | | 22.1 | Marlboroug | gh, | | | | 13.1 |

* One year,

1894 and 1895.

† The terms "urban" and "rural" as here employed refer to the 39 cities and towns enumerated in this table for the "urban" class, and to the remaining population Nore .- The population stated in this table is that of the State Census of 1895, but the mean population employed for computing the marriage, hirth and death rates, ete., is obtained by estimating the population of each city and town for the year 1894, upon the rate of growth from 1890 to 1895, and then taking a mean of the two years for the "rural."

Table 70 - Concluded.

STATISTICAL SUMMARIES

03

DISEASE AND MORTALITY.

STATISTICAL SUMMARIES OF DISEASE AND MORTALITY.

The statistical information received by the Board during each year, either through the medium of voluntary returns or in consequence of legal requirements, has, in the last two reports of the Board, been presented under four different heads or groups, which were summarized and defined in the last report as follows:—

- 1. The Weekly Mortality Returns. These consist of the reports of deaths, which are made up weekly and are sent to the office of the State Board by the registration officials of cities and towns. They are voluntary, and serve principally to show the seasonal prevalence of each of the chief infectious diseases, and the mortality of children under five years old in weekly periods. This series of statistics has been continued by the Board for at least twenty years, and has been published as a summary for fourteen years.
- 2. The Reports of Certain Infectious Diseases, Diphtheria and Croup, Scarlet-fever, Typhoid Fever and Measles. These are obtained from the annual reports of local boards of health for the year 1896, which are forwarded to the State Board from cities and towns. By comparing the numbers of reported cases with the reported deaths, the mean fatality of each disease in the places from which the reports are made is obtained with a reasonable degree of accuracy.
- 3. Reports of Cities and Towns, made under the Provisions of Chapter 302 of the Acts of 1893. By this act each local board of health is required to report to the State Board every case of "disease dangerous to the public health" which is reported to the local board. A digest of these reports is presented in summary No. III.
- 4. Reports made under the Provisions of Chapter 218 of the Acts of 1894. The full reports of deaths occurring in each city and town having over 5,000 inhabitants comprise another series of returns, which are summarized in No. IV. These reports are made under the requirements of the following statute:—

[ACTS OF 1894, CHAPTER 218, SECTION 3.]

"In each city and town having a population of more than five thousand inhabitants, as determined by the last census, at least one member of said board shall be a physician, and the board shall send an annual report of the deaths in such town to the State Board of Health. The form of such reports shall be prescribed and furnished by the State Board of Health."

I.

SUMMARY OF THE WEEKLY MORTALITY REPORTS FROM CITIES AND TOWNS.

The following summary comprises the returns of deaths made at the end of each week by the town clerks, city registrars and other officials having in charge the vital statistics of cities and towns.

These returns are compiled each week and published as a bulletin, one copy of which is sent to the registering officer of each city and town in the State. These reports are necessarily incomplete, since they are voluntary, and comprise the mortality statistics of a part of the population only, the reporting places being chiefly the cities and larger towns. The value of the weekly mortality returns consists very largely in the fact that they constitute a continuous history of the prevalence of the principal infectious diseases throughout the State, so far as can be learned from the mortality which they cause.

In connection with the results of the information obtained as a consequence of the enactment of chapter 302 of the Acts of 1893, these weekly mortality reports furnish to the Board an important index of the health of the people, as influenced by the prevalence of epidemic diseases at different seasons of the year. The estimated population of the cities and towns contributing to the returns of 1896 was about 1,486,000, or about three-fifths of the total population.

The data embraced in this summary are the following: -

Average height of barometer for each week.

Mean maximum temperature.

Mean minimum temperature.

Rainfall expressed in inches.

Total deaths reported for each week.

Deaths of children under five years.

Deaths from infectious diseases.

Deaths from consumption.

Deaths from acute lung diseases.

Deaths from typhoid fever.

Deaths from diarrhæal diseases.

Deaths from scarlet-fever.

Deaths from measles.

Deaths from diphtheria and croup.

Deaths from puerperal fever.

Deaths from malarial fever. Deaths from small-pox.

Deaths from whooping-cough.

Deaths from erysipelas.

In consequence of the unusual amount of space devoted to the vital statistics of the State in this report, the usual summary of the facts contained in the following table will be omitted this year, but will be presented, together with that of other years, as a general summary in a succeeding volume.

The following table contains a summary of the statistics compiled from these weekly returns of mortality:—

II.

FATALITY (*RATIO OF DEATHS TO CASES*) FROM CERTAIN INFECTIOUS DISEASES IN 1896.

The statistics presented in the following table are compiled from the published reports of local boards of health for the year 1896 which have been forwarded to the office of the State Board of Health. They are the figures representing the numbers of cases reported to local boards of health under the provisions of section 79 of chapter 80, Public Statutes.

The numbers of deaths are also obtained from the same reports, and the comparison of these two series of figures presents a fairly accurate method of arriving at the fatality from these diseases in the places from which they are reported. The figures representing the numbers of cases are probably less than the actual numbers, since some cases must necessarily escape registration through neglect to report or in consequence of faulty diagnosis.

Cases of Infectious Diseases and Deaths reported to Local Boards of Health, 1896.

^{||} Whooping-cough, 2 cases.

The cities and towns embraced in the foregoing table are 78 in number, or 6 less than those presented in the previous year. They comprise at least three-fourths of the population of the State.

The reported cases from diphtheria and croup were in excess of those of any of the previous years embraced in the report, but the actual number of deaths was less than that of either of the two preceding years and the fatality was also less, being only 15.1. Comment upon these figures will be found elsewhere.

The reported cases of scarlet-fever were much less than those reported in 1895, and the fatality (5.7 per cent.) was less.

The reported cases of typhoid fever were greater than those of 1895, and the fatality (15.6) was less than that recorded in any previous year.

The reported cases of measles were in greater number than those of any previous year, but the fatality (0.9) was less.

The figures for 1896 are as follows: -

| Reported cases of diph Registered deaths from Fatality (per cent.), | diph | ther | ia an | d ero | ap in | the s | ame | cities | and | town | 8,915 1,348 15.1 |
|--|------|-------|-------|--------|--------|--------|--------|--------|------|------|------------------------|
| Reported cases of scarl Registered deaths from Fatality (per cent.), | scar | let-f | ever | in the | e sam | e cit | ies ar | id tov | vns, | | 3,873 220 5.7 |

For the purpose of convenience in future reference the table relating to diphtheria and croup is here divided into two periods, which may properly be called the pre-antitoxin and the antitoxin periods, since antitoxin came into use in the State about the beginning of the year 1895.

In order to compare the foregoing figures with those of another country in which systematic notification has been conducted for a

period of several years successively, the following figures for England are also presented, as given in the annual reports of the Local Government Board:—

England. [Local Government Board figures.]

| | | | | | | DIPHT | HERIA. | CRO | UP. | Тот | ral. | |
|--------|--------|-------|------|-------|---|--------|---------|--------|---------|--------|---------|-----------|

| Typhoid fever, | | | | | 19.9 | 20.8 | 17.8 | 17.0 | 17.5 | 16.9 |

III.

Official Returns of Notified Diseases Dangerous to the Public Health, 1896.

The following summary embraces the returns of diseases "dangerous to public health," made to the State Board of Health under the provisions of chapter 302 of the Acts of 1893. Since the act in question did not specify the diseases intended to be reported to the Board (except small-pox), the Board issued a circular, in which it expressed its opinion as to the particular diseases which should be reported under the provisions of this act. They were the following: small-pox, scarlet-fever, measles, typhoid fever, diphtheria, membranous croup, cholera, yellow fever, typhus fever, cerebro-spinal meningitis, hydrophobia, malignant pustule, leprosy and trichinosis.

The report of 1893 embraced the returns of the fractional year only which immediately followed the enactment of the statute, while those of 1894 and 1895 were each for a full year.

The whole number of cases of infectious diseases reported in 1896 was 21,320, which were divided as follows:—

| Reported cases | of | small-p | ox, | | | | | | 5 |
|----------------|----|---------|-------|-----|--------|---|--|--|------------|
| Reported cases | of | diphthe | ria s | ind | eroup. | , | | | 8,515 |
| Reported cases | | | | | | | | | 3,801 |
| Reported cases | | | | | | | | | 2,637 |
| Reported cases | of | measles | 5, | • | | | | | 6,362 |
| Total, . | | | | | | | | | 21,320 |

The summary for the years 1893, 1894, 1895 and 1896 is as follows:—

| | | | | | | | Rei | PORTED CASES | OF | |
|------------|-----|-----|------|------|--|------------|--------------------------|--------------------|-------------------|----------|
| | | | | | | Small-pox. | Diphtheria and Croup. | Scarlet- fever. | Typhoid Fever. | Measles. |
| 1893 (four | mor | ths | only |), . | | 35 | 1,109 | 2,914 | 1,525 | 1,503 |
| 1894, . | | | | | | 181 | 4,178 | 6,731 | 2,372 | 2,133 |
| 1895, . | | | | | | 1 | 7,806 | 6,194 | 2,438 | 4,868 |
| 1896, . | | | | | | 5 | 8,515 | 3,801 | 2,637 | 6,362 |
| Total, | | | | | | 222 | 21,608 | 19,640 | 8,972 | 14,866 |

Seasonal Distribution. — By months these diseases were reported as follows in 1896:—

Cases of Infectious Diseases reported to the Board by Months during 1896.

| | | | Diphtheria. | Scarlet-fever. | Typhoid Fever. | Measies. | | | Diphtheria. | Scarlet-fever, | Typhoid Fever. | Measies. |
|----------|---|---|-------------|----------------|----------------|----------|------------|--|-------------|----------------|----------------|----------|
| January, | | | 898 | 407 | 144 | 346 | August, . | | 522 | 189 | 321 | 177 |

| December, | | | 26.5 | 11.4 | 16.9 | 12.9 | 12.4 | 7.8 | 7.2 | 10.0 | 9.2 | 34.6 | 19.9 | 6.8 |
| Mean, | | ٠ | 23.3 | 10.0 | 10.0 | 10.4 | 10.0 | 10.0 | 7.2 | 10.0 | 10.0 | 17.4 | 10.0 | 10.0 |

The figures in the foregoing table are introduced for the purpose, not of comparing the prevalence of one disease with another, but for

the purpose of presenting the reports of each month upon a uniform basis of comparison, month by month, so that the relative intensity of each disease is shown for each month. The method also has the advantage of eliminating the apparent errors of computation arising from the unequal length of the months.

The figures may be read as follows: for example, the mean daily number of reported cases of diphtheria and croup in January, 1896, was 29.0; of scarlet-fever, 13.1; of typhoid fever, 4.6; and of measles, 11.2 (see columns marked A); and the mean daily number of the same diseases for the whole year 1896 was, respectively, 23.3, 10.4, 7.2 and 17.4. Assuming a standard of 10 as the daily mean of each disease for the year, the ratios for January were as follows: diphtheria and croup, 12.4; scarlet-fever, 12.6; typhoid fever, 6.4; and measles, 6.4 (see columns marked B). That is to say, for each 10 reported cases of diphtheria and croup occurring throughout the year, as a daily mean, there were 12.4 daily in January, 11.3 in February, etc.

The following table presents the numbers of cases of each disease reported from each city and town in 1896. The whole number of reporting cities and towns is less than that of the previous year.

Where the name of a city or town occurs both in Section II. and in Section III. of this summary, the difference in numbers may be taken as the deficiency in returns made by the local board to the State Board of Health.

Cases of Infectious Diseases reported to the State Board of Health from One Hundred and Forty-four Cities and Towns during 1896.

The following list comprises the cities and towns which failed to report (under the provisions of the statute) to the State Board of Health. It is but just to state that in many of the towns named in group IV. and in some of those in group III. it is quite probable that no cases of infectious disease occurred.

LIST OF TOWNS FROM WHICH NO REPORTS WERE RECEIVED.

I. Cities.

CHICOPEE, HOLYOKE.

II. Towns having a Population of More than 5,000 in Each.

Andover, Athol, Blackstone, Framingham, Gardner, Greenfield, Melrose,

Methuen.

Montague,
Natick,
North Attleborough,
Orange,
Palmer,
Plymouth,
Revere,
Rockland,

Southbridge, Spencer, Stoneham, Wakefield, West Springfield, Winchester.—22.

Rehoboth.

III. Towns having a Population of Over 1,000 but Less than 5,000 in Each.

Freetown,

Abington, Acton, Acushnet. Agawam, Ashburnham, Ashfield, Ashland, Bellingham, Belmont, Billerica. Bourne, Bradford. Brookfield. Buckland, Canton, Carver. The Board will forward to the local board of health of any place the postal cards necessary for reporting, on application from such local board of health.

IV.

Official Returns of Deaths in Cities and Large Towns (Chapter 218, Acts of 1894).

The following summary comprises the results obtained from the tabulation of the returns required by chapter 218 of the Acts of 1894, whereby the board of health of each city and populous townis directed to send to the State Board of Health an annual statement of the deaths in such city or town upon a blank form furnished by the State Board.

The whole number of cities and towns included in this list is 85, of which number all except the town of Montague complied with the statute. The total population of these 85 cities and towns by the census of 1895 was 2,034,658.

In consequence of the failure of Montague to send a return, as required by statute, the figures for that town have been copied from the published report of the town clerk for the year 1896.

The death-rates of these towns in the following summary for the year 1896 are calculated upon an estimated population, such estimate being based upon the rate of growth from 1890 to 1895, as taken from the census returns.

This estimate would add one more town to the list for 1896 (Williamstown), and the returns of this town are included in the summary, although not required by the statute, making the total number of towns included in the summary 86.

The estimated population of these 86 towns in 1896 was 2,093,820, or about 80 per cent. of the total population of the State.

The whole number of deaths registered in these towns in 1896 was 40,400, and the death-rate calculated upon the foregoing estimated population was 19.29 per 1,000 living. This rate was slightly higher than that of 1895.

Sexes. — The number of deaths of males was 20,530, or 50.9 per cent. of the whole number of deaths; and the deaths of females were 19,834, or 49.1 per cent. of those whose sex was known. There were 36 in which the sex was not stated in the returns.

Ages. — The deaths shown by four groups of ages, as recommended by Körösi, were as follows:—

| 1.0-0 | D | eaths. | | AGES OF EATHS. | Agna | Deaths. | PERCENT ALL D | AGES OF EATHS. |
|---------------|-----|--------|-------|-------------------|--------------|---------|------------------|-------------------|
| AGES. | 11: | 896. | 1896. | 1895. | Ages. | 1896. | 1896. | 1895. |
| Under 1 year, | . 1 | 0,073 | 24.97 | 22.9 | 20-50, | 10,074 | 24.97 | 25.7 |
| 1-20, | • | 7,159 | 17.75 | 17.9 | 50 and over, | 13,031 | 32.31 | 33.5 |

The deaths of infants under one were 10,073, or 24.97 per cent. of the total mortality, and those of children under five years were 14,475, or 35.88 per cent. of the total mortality. The number of deaths of infants under one year and that of persons between the ages of twenty and fifty years were nearly identical.

All of the percentages in this table are estimated upon the number of deaths of persons whose ages were specified in the returns. The total number of deaths in which the age was not specified was 63.

Months and Quarters. — The number of deaths in each quarter of the year is shown in the following table: —

| | Deaths. | PERCEN | TAGES. | | Deaths. | PERCEN | TAGES. |
|-------------------|---------|--------|--------|-------------------|---------|--------|--------|
| | 1896. | 1896. | 1895. | | 1896. | 1896. | 1895. |
| First quarter, . | 9,524 | 23.58 | 26.9 | Fourth quarter, . | 8,829 | 21.85 | 23.0 |
| Second quarter, . | 9,682 | 23.97 | 22.7 | Date unknown, . | 5 | - | - |
| Third quarter, . | 12,360 | 30.60 | 27.4 | Total, | 40,400 | 100.00 | 100.0 |

The intensity of the seasonal death-rate is shown in the following table, the method employed being explained on page 846, in Section III., relating to disease notification.

Seasonal Intensity of the Death-rate.

| | Mean Daily Deaths per Month. | MEAN R COMPARED STANDARD | WITH A | | Mean Daily Deaths per Month. | MEAN R COMPARED STANDARD | WITH A |
|-------------|------------------------------------|--------------------------------|--------|--------------|------------------------------------|--------------------------------|--------|
| | 1896. | 1896. | 1895. | | 1896. | 1896. | 1895. |
| January, . | 100.29 | 90.84 | 96.2 | August, | 143.94 | 130.38 | 122.0 |
| February, . | 106.07 | 96.08 | 120.8 | September, | 111.27 | 100.79 | 105.8 |
| March, . | 107.71 | 97.56 | 111.7 | October, | 97.19 | 88.03 | 91.7 |
| April, . | 114.27 | 103.51 | 101.8 | November, | 90.73 | 82.18 | 91.5 |
| Мау, | 106.23 | 96.22 | 89.9 | December, | 99.81 | 90.41 | 91.1 |
| June, | 98.70 | 89.40 | 80.9 | Annual mean, | 110.40 | 100.00 | 100.0 |
| July, | 147.10 | 133.24 | 98.2 | | | | |

Causes of Death. — The list of causes of death embraced in the summary includes those from the principal infectious diseases, including consumption, together with certain other groups of destructive diseases and those from violence.

The ratio of deaths to the living population is also presented, since this method of presentation constitutes a better method of indicating the incidence of each cause of death upon the living population than the ratio of the deaths from each disease or cause of death to the total mortality.

The population upon which the foregoing death-rates are calculated is estimated for 1896 by the usual rule, from the rate of increase in the foregoing five-year period (1890-95).

HEALTH OF TOWNS.

[867]

HEALTH OF TOWNS.

ADAMS.

Diphtheria seemed to show itself in an epidemic form through the months of September, October and November, and was reported from various localities in the town, while every effort on the part of the board was made to prevent the spread of the disease. Antitoxin as a treatment was used in many cases with very favorable results. Scarlet-fever was a very rare disease for the year, there being only two cases reported. The mortality was marked by consumption, cholera infantum, pneumonia and diphtheria, and exceeds that of last year, other diseases included, by forty deaths.

AMESBURY.

The number of complaints of nuisance has not been large, and we believe each one was promptly attended to.

We have been exceedingly fortunate in having only two deaths from contagious diseases this year, as compared with fourteen in 1895.

The past year we have kept a supply of antitoxin on hand, and it has been furnished the physicians as they needed to use it. The experience of most of our physicians is that antitoxin is by far the most valuable agent we have at present for the cure of diphtheria. Sometimes one injection is sufficient; at other times two or even three are used at intervals of twelve to twenty-four hours, using from seven to ten cubic centimeters for a dose. The membrane seems to soften and grow thin, the fever and pulse rapidly assume the normal condition and convalescence is rapidly established.

ARLINGTON.

This year, like the last one, has been free from cause for alarm from any epidemic of dangerous or contagious diseases.

Among occurrences of the year now closing, in a sanitary point of view, of greatest importance is the rapid progress which has been made in the construction of our public sewers and connection of same with the metropolitan system, which now serves a large portion of our town.

Spy Pond has always been notable in the history of our town, and of great interest to our citizens for purposes of recreation and the commercial value of its product of ice. Of late years the problem of how to purify its waters has engaged the attention of citizens and local organizations.

ATHOL.

There has been a disposition among some property-holders not to comply with the laws, but on the whole there has been a general spirit of co-operation manifested by the citizens in the work of the board. Understanding the effects of the hard times the board has modified its requirements regarding certain by-laws, and endeavored to be as lenient with the property-holders as the health and safety of the public would allow.

Although a system of sewerage extends through most of the streets of the town, there seems to be a disposition among some of the propertyholders not to utilize it and connect their premises with the sewers. The number of sewer connections ordered has been fifty.

There have been issued one hundred and twelve permits for plumbing.

ATTLEBOROUGH.

It is interesting to note that the antitoxic serum for the treatment of diphtheria was first used during the year, and that in the two fatal cases it was not employed, the physicians in each case being called too late.

Next to pneumonia, the disease causing the largest number of deaths is consumption.

BELMONT.

During the year there has been no serious epidemic of contagious disease. A mild epidemic of measles in the spring necessitated the closing of one of the schools, but no deaths have occurred in the past year from any contagious disease.

BOSTON.

The total number of deaths for the year was 11,634, an increase over the previous year of 305 deaths. The death-rate for the year was 22.53 per 1,000 inhabitants. This rate is less by .07 than that of the previous year, and the lowest since 1884. There were 1,985 deaths from zymotic diseases, an increase of 17 deaths over the same group of the previous year. There were 72 less deaths from diphtheria than in 1895, although the number of cases of diphtheria reported was largely increased on account of the larger number discovered among the pupils in the public schools by the medical inspectors of schools, and the bacteriological tests in the otherwise unrecognized cases. The ratio of deaths to the number of cases of diphtheria reported was 11.49 per cent., as against 14.48 per cent. the preceding year. There were 121 deaths from scarlatina, 7 more deaths than in the preceding year, and 72 less than the average of the five previous years. Typhoid fever caused 162 deaths during the year. There were 19 deaths from measles during the year. The number of deaths of children under five years of age was 4,055, compared with 3,935 for the previous year, showing an increase of 120 deaths.

The medical inspection of schools has been continued during the past year, with the same encouraging and satisfactory results as during the previous fourteen months. All pupils who have complained or appeared to their teachers to be ill have been examined by the visiting physicians, and the teachers advised as to what should be done with such pupils. The teachers and visiting physicians have entered upon and pursued this work with surprising harmony. The search for infectious diseases in the schools during the last year has been even greater, while the number of cases in this class found in 1896 is less than that of 1895. The same is true also of the other miscellaneous diseases. Considerable inquiry has been made by officials of other cities as to our methods and results in this work, and several cities, including New York, are now preparing to adopt a similar system of inspection in their schools.

For the year ending Dec. 31, 1896, the whole number of pupils examined was 8,964, and of this number 1,156 were found to be too ill to remain in school. The diseases found may be classified as follows:—

| Specific infecti | ious di | iseas | ses, | | | | | | 267 |
|------------------|---------|-------|--------|------|----|--|---|--|-------|
| Oral and respi | iratory | dis | eases, | | | | | | 3,934 |
| Ear diseases, | | | | | | | | | 66 |
| Eye diseases, | | | | | | | | | 382 |
| Skin diseases, | | | | | | | | | 628 |
| Miscellaneous | diseas | ses, | | | | | | | 3,687 |
| Total num | nber o | f ex | amina | tion | s, | | , | | 8,964 |

Much work is reported by the board as having been accomplished during the year in the line of school-house sanitation, improvement of the condition of exposed tide-water flats near the city, and house-to-house inspection.

Number of houses ordered to be vacated, 121. Many of them were afterward put in good condition and were allowed to be occupied.

| Disinfection in infectious | disea | ses, | total | numb | er, | | 5,229 |
|----------------------------|--------|------|-------|------|-----|--|--------|
| Rooms disinfected, . | | | | | | | 9,967 |
| Sulphur used (pounds), | | | | | | | 44,348 |
| Nuisances abated by disin | nfecti | on, | | | | | 41,686 |

The steam disinfecting apparatus at Swett Street has been in constant use throughout the year.

The board proposes to supersede the old method of room disinfection by sulphur, and to employ formaldehyde gas in its place.

The board renews its recommendation for the provision of improved means for disposing of garbage and offal.

The total number of baths taken at the different public sea-water bath-houses in 1896 was as follows:—

| Men and boys, . | | | | | | | | |
|------------------|---|---|---|---|---|---|---|---------|
| Women and girls, | • | • | • | • | • | • | • | 189,341 |
| Total | | | | | | | | 901 925 |

The board reports fully upon the following topics: licensing of plumbers and undertakers, issue of burial permits, approval of lodging-houses, paving of courts and alleys, removal of night-soil, assignment of offensive trade locations, inspection of lying-in hospitals, and bakeries.

BROOKFIELD.

The general health of the community has been excellent, and no death has occurred from scarlet-fever, diphtheria or typhoid fever, and, in fact, these diseases have not appeared in town, except three isolated cases of typhoid fever, with one exception probably contracted outside of the town.

BROOKLINE.

Thorough disinfection after scarlet-fever and diphtheria has been done by the board after the recovery or death of the patient, but it has not returned to the use of sulphur fumes for disinfection, except when specially requested, when it is used in conjunction with more reliable means.

Intermittent fever (malaria) has continued to be somewhat prevalent in Brookline, as well as in all the adjoining municipalities. Under the provisions of chapter 80 of the Public Statutes the board of last year ordered the abatement of a nuisance consisting of wet and boggy lands lying between Woodland Road and Heath Street. This order has been complied with, under supervision of the town engineer.

The board of health hospital buildings for diphtheria and scarlet-fever have been in use much of the time, and by providing a suitable place for the isolation and care of the first cases occurring in tenements and other crowded dwellings, have doubtless done much to prevent these dangerous but more or less preventable diseases from becoming epidemic, and at the same time have enabled many children to continue in school who otherwise, though well, must have remained out for many weeks.

The number of cases of typhoid fever was larger than usual, but all were of a rather mild type, and some of them were imported from Florida and elsewhere.

The ice supplied the citizens was inspected from time to time, and specimens subjected to bacteriological examination were found free from disease germs.

The need of improved public bathing facilities, recommended in previous reports of this board as an important health measure, has been recognized by the town, and the little swimming tank in the Village Brook has been succeeded by a new public bath, located in the centre of population, and in every respect worthy of the town.

CAMBRIDGE.

| Number of | inspe | ction | s ma | de, | | | | | 3,941 |
|-----------|-------|-------|--------|--------|------|--|--|---|-------|
| Number of | subse | quen | t insp | pectio | ons, | | | | 4,329 |
| | | | | | | | | | |
| Total, | | | | | | | | 4 | 8,270 |

The need of hospital accommodation for cases of infectious diseases dangerous to the public health is still as pressing as ever, and the attainment of this accommodation is apparently as remote. Cambridge has yet to learn that money can be expended in no better way than in providing means for the isolation of cases of diseases that imperil the public health by their infectious nature.

We have in our previous reports shown the necessity for the work of a bacteriologist, and this portion of our work is now, we hope, established on a somewhat permanent basis.

Medical Inspection of Schools.—The city was divided into six school districts, the number of schools in a district varying from five to seven, depending on the distance to be covered by the inspector in his daily round and upon the number of scholars in the schools visited.

The following instructions, a copy of which was sent to each inspector, indicate the lines upon which the inspections are conducted:—

- 1. The physician is to examine only such children as are indicated to him by the teacher as having complained, or as appearing to be suffering from disease.
- 2. The physician is to recommend to the principal to send home immediately any child whom he may suspect of having any infectious disease.
- 3. The physician must not recommend the employment of any special physician or mode of treatment for the particular case.
- 4. In case of near-sightedness or other trouble with the eyes, or deafness or other car trouble, to which attention has been directed by the teacher, the physician is instructed to suggest that the principal recommend to the parents that the eyes or ears of the pupil be examined.

The report of the inspector of ice for 1896 indicates that in several instances the danger from past or present pollution of the supply is so great as to render it necessary to prohibit the sale in this city for domestic use of ice which is derived from such impure sources. The following are strong instances of such impure sources of supply:—

" Horn Pond, Woburn, Mass.

"The northern shore of this pond is thickly settled. A small brook flows into the upper end, which brook also flows through a part of the town and receives the drainage from a number of barn-yards. The danger of contamination of the water from the large population settled on the water-shed is so great as to make it an unsafe one to use for an ice supply.

"A considerable excess of chlorine above that which is the normal of the region indicates a past or present pollution of the water. The normal chlorine of this region is, according to the State Board of Health, 0.30 per 100,000 parts. The report of the inspector shows that the chlorine in the water of this pond is 1.40 per 100,000, and his personal inspection is, we think, conclusive that the excess cannot be attributed to a source of pollution that has ceased to exist."

" Lake Quanapowit, Wakefield, Mass.

"The town of Wakefield borders on one end and side, a cemetery on part of the other side. The water-shed of this pond supports far too large a population to make the pond a suitable one from which to cut ice for domestic use. Chlorine, 1.35 per 100,000. Normal chlorine of this region, 0.38."

" Spy Pond, Arlington, Mass.

"The northern shore is high and entirely taken up with dwelling-houses. Two drains, apparently for surface water only, were seen emptying into the pond on this shore. The other banks are, with the exception of a grove on the southern shore, taken up with market gardens and with numerous houses close to the water. The danger of contamination is considerable, especially from drainage from the market gardens, on which large quantities of manure are used, much of it, I am informed, consisting of night-soil. Chlorine, 2.50 per 100,000. Normal chlorine of this region, 0.40."

"Smith's or Little Pond, Belmont, Mass.

"Two brooks flow into it; one draining Spy Pond, the other draining the low land between Belmont and Arlington, which is largely given up to market gardens. The pond empties through Little River into Alewife Brook. Two colonies of bacillus coli communis developed during the examination of the water, which is strong evidence of sewage contamination. Chlorine, 9.10 per 100,000. Normal chlorine of this region, 0.40."

" Sandy Point, Ayer, Mass.

"There are a few houses at the lower end, and on one bank is an apparently but little used picnic ground with a privy about ten or twelve feet from the shore. Chlorine, 0.40 per 100,000. Normal chlorine of this region, 0.15."

"Waushakum Lake, South Framingham, Mass.

"There are several picnic houses around the shore, and quite a large picnic grove on one side. A small dwelling-house is close to the shore near the ice-houses. Chlorine, 0.50 per 100,000. Normal chlorine of this region, 0.23."

The above quotations from the report of the inspector of ice, showing clearly as they do the pollution of many of the sources of ice supply, afford the amplest confirmation of the position taken by the board in its recommendation above referred to, as to the necessity for making such inspection of those sources of supply.

In accordance with the provisions of chapter 418 of the Acts of 1896, the various bakeries in this city have been inspected, and a printed copy of the act posted in each bakery and place in which the business mentioned in said act is carried on.

CHICOPEE.

Since September 1 there has been a marked increase in the number of cases of diphtheria and croup, thirty-five being reported for November and the same number for December. In some instances the quarantine was disregarded, and it is quite evident that some of this sickness might have been prevented had it been properly respected; it is, therefore, imperative that rigid measures should be taken to enforce its observance. Antitoxin treatment in a number of cases has met with very satisfactory results.

No provision has yet been made by the city authorities for the removal of garbage and other refuse, which is a constant menace to the public health. During the winter season it accumulates in frozen masses, while each day fresh and liberal additions are made, particularly in the thicker settled sections, until the spring arrives and the health officer again appears to assume the duties of the coming season. The introduction of some system that would be thorough and effective is the only way to overcome this monstrous form of filth.

CLINTON.

With reference to diphtheria the board feel that what was recommended last year voices substantially their position this year in the matter, *i. e.*, that the use of antitoxin is of undoubted merit, and should be begun early in the disease.

Concord.

We have endeavored to procure the passage of a bill in the present Legislature permitting the board to inspect the houses owned by the State and occupied by the officers of the Massachusetts Reformatory in this town. As the result of a hearing we were given leave to withdraw, and the case now stands as before we acted. We have no rights in any of the above houses, either to inspect or to investigate upon the occurrence of any contagious disease, to quarantine or to fumigate.

The matter of more thorough sanitation in barns where cows are kept is receiving considerable attention all over the State, in view of the well-known intimate connection between tuberculosis in cattle and poor ventilation of barns. We feel, therefore, that this matter should be attended to the coming year. Its importance is clearly manifest through a communication from the city of Cambridge inquiring about the general sanitary condition of some fifty farms in this town where milk is produced and sold to dealers in Cambridge. The questions are very searching, as they have traced the two epidemics of typhoid fever occurring last summer and fall to the carelessness of the milk peddler in handling the cans. Naturally they

desire to know more about the sources of their milk supply. We have decided to have our agent, in his annual tour of inspection in the spring, report more fully with reference to the condition of the milk supply, in order that we may determine in what way the conditions may be improved and what can be done, either by regulation or inspection, to make the general conditions better.

DANVERS.

The diphtheria antitoxin of the State Board, which is kept on hand by our board, has been quite largely used, also the culture tubes for the diagnosis of diphtheria. Diagnosis of cases of diphtheria by means of these tubes is reported from the State Board inside of thirty-six hours after the culture has been sent from Danvers.

In a former report the board stated that the only satisfactory solution of the disposal of sewage was for the town to have a sewer system. The present board is of the same opinion, and would urge the town to take steps towards having such a system in the near future.

DEDHAM.

The cases of contagious diseases reported during the past year have been 45 in number, which, by comparison with the record for the preceding year of 98 cases, shows a relative improvement in public health. There were 15 cases of diphtheria in 1896, and the decrease in the number of cases of diphtheria from that recorded for the preceding year, there being 56 cases in 1895, is of special interest.

EVERETT.

The city is in as good sanitary condition as last year.

There has been some impatience on account of the length of time that persons have been kept in quarantine in cases of diphtheria. The virulence of the germs has been tested in these protracted cases, and it has been found that the bacilli are as virulent as in the early stages. Therefore it is the only safe rule to keep the patient quarantined until the bacilli do not appear. We believe that every case is due to infection, either from some infected person or article. Of 60 cases in which antitoxin was used all but one were proven to have bacilli, or else were in families where others had diphtheria. Of these there were 5 deaths, a mortality of 8 per cent. Of 30 cases where it was not used a culture showed bacilli present in 20 cases. There were 6 deaths, a mortality of 20 per cent.

FALL RIVER.

All houses in which contagious diseases are reported to exist are immediately visited and the occupants furnished with circulars containing instructions and reliable information upon the precautions to be taken to

stay the spread of that particular disease. In cases of diphtheria and scarlet-fever, cards, designating the disease, are attached to the building, at every door; and in all cases a thorough inspection of the sanitary condition of the building and premises is made; all reports and complaints received through the police department or from citizens are subject to a thorough investigation; when an owner of property has any reason to suspect that the plumbing or the drainage system of the same is unsafe, an inspection is promptly made; when a new sewer is laid in a street previously unsewered, every building situated upon a line of said sewer is visited and inspected, and if upon such inspections it is found that any conditions exist inconsistent with the rules and regulations of the board, an order is immediately served upon the owner, calling upon him to abate such nuisances, reconstruct plumbing or otherwise conform to the rules and regulations, in accordance with the city ordinances and the Public Statutes.

The board supplies the means whereby physicians can determine exactly whether or not any doubtful case of throat disease is or is not diphtheria, by providing the facilities necessary for an expert bacteriological examination of cultures taken from the throat of suspected patients. For this purpose, boxes containing culture tubes, swabs and full printed instructions for taking cultures, with blank form to make a report upon, are distributed at drug stores throughout the city.

The number of persons successfully vaccinated at this office during the past five years was 8,396.

FITCHBURG.

The number of written notices issued requiring the action of the board was 527. This includes the general notices regarding nuisances, construction of cesspools, orders to connect with the sewer, defective plumbing to be remedied, and many others of miscellaneous character.

The board has found the schools to be the most likely source of contagion in many cases, most of the cases being among scholars or families of scholars attending school. In several different instances it has been thought advisable to fumigate and disinfect the school buildings, and this has had a noticeable effect in checking the spread of contagion.

FRANKLIN.

We have attended promptly to such complaints as have been brought before us, and have ordered such action as seemed to be called for in each case. It is a pleasure to report that we have found citizens ready to cooperate cheerfully with this board in maintaining the health of the town, and our business has been transacted without friction or unpleasantness.

GARDNER.

Considering the number of cases of diphtheria, and the severity of nearly every case, it is remarkable that there were not more deaths, only one being reported. To a certain degree this is owing to the use of antitoxin. It was administered in seven cases, some of them having seemingly only a few hours to live. Every case where it was used recovered. The board of health took active measures to limit the spread of contagious diseases, and we feel our efforts were more or less successful.

GLOUCESTER.

We consider the sanitary condition of our city very fair, with the exception of a few localities. Privy vaults and cesspools continue to be an intolerable nuisance, and are, we believe, directly responsible for a great deal of avoidable sickness. A system of sewerage is the only remedy for the existing pernicious state of affairs.

HAVERHILL.

The method of disposal of refuse, animal, vegetable and mineral, is giving the board the usual trouble, and will probably continue to do so until an ideal method of disposal is found.

The board renews its annual statement as to a hospital for contagious diseases, required by law, still uncomplied with.

The middle of June, in which there are usually no cases of this disease, found the city suffering from an epidemic of typhoid fever, though fortunately not of a very fatal character. Not since the introduction of our present water supply has there been in any season so many cases in the city as occurred during the summer and autumn months of 1896. One hundred and one cases have been reported from the middle of June to the close of the year, 90 or more of which had their direct origin in the city.

The following extract is from Professor Sedgwick's report: "It became evident that two-thirds of all the cases, excluding imported cases and cases of earlier date, were located upon one of the water supplies, namely, that derived from Crystal Lake. I therefore visited the lake and examined its sanitary condition, and I regret to say that the results of my inspection, while they show that the lake has a good natural watershed, which might be easily guarded and kept in good sanitary condition, indicate that at the present time proper safeguards do not exist; and it is entirely possible that from the more or less public uses of the lake for pleasure purposes, some contamination may have come which caused the present epidemic. I am informed that a part of the shore is used for picnic grounds; a cottage or club-house with its sink-spout and its privy stands very near the lake, not far from the intake of the water works; boating on the lake appears to be common; and other evidences exist of improper use of the shores. There

is no positive evidence of any contamination of the lake by any one having typhoid fever; but it is well-known that 'walking' cases of this disease are not uncommon, and it may be that such a contamination has actually occurred. In any case there can be no doubt that the city of Haverhill should own and control not only the lake but its entire shores. A lake which supplies drinking water to a modern city should not be used for boating, fishing or swimming; nor its shores for cottages or picnic grounds; and until Crystal Lake can be entirely rescued from its present uses by the miscellaneous public, those who drink the water derived from this source would do well to boil and cool it before drinking. I have also visited and inspected Round Lake and its environs, and I am of the opinion that the use of its shores for ice-houses, stables, etc., as at present conducted, is improper, and constitutes a menace to the public health."

IPSWICH.

A few words in regard to the sanitary condition of the town; we consider that it is in a good condition, taking everything into consideration. We have had considerable complaint from overflowing cesspools during the year, a matter which we expected, owing to the large usage of water; but we think this will be obviated in the future and that we shall have very little trouble from this source.

LEXINGTON.

The vexed question of piggeries seems to have been settled, and we are gratified to say that no complaint has been made in that direction for a long time. The board, however, is well aware that the swine-keeping industry in this town must be carefully watched, and in this connection we know, from much time, trouble and labor expended by us in the past, that "eternal vigilance" is the price of health; hence we cordially invite cooperation by the citizens toward the regulation of this somewhat unsavory traffic; and co-operation in this manner, — not by complaint in an unofficial form to the casual listener, but by direct complaint in writing to this board.

LOWELL.

| | | | | | | 169 | 9 |

^{*} Saving in 1896 of \$319.19.

During the year 1896, 33,389 loads of ashes were removed from houses and stores to the various dumping grounds in use.

Sixty-five bakeries were inspected by the board under the act of 1896.

The number of physicians who have availed themselves of the bacteriological test has largely increased, and the results have given general satisfaction. There have been one or two cases when the physician has doubted the result of the bacteriological report, considering the case to be simple follicular tonsilitis, and where the examination proved the case to be diphtheria. In last year's report it was suggested that a negative bacteriological examination be made before a case with diphtheria be released from quarantine. The most approved custom is that there shall be two negative reports before the case be released.

Diphtheria cases where antitoxin was used: Cases, 31; recovered, 28; died, 3; per cent. of deaths, 10.

Diphtheria cases where antitoxin was not used: Cases, 79; recovered, 35; died, 44; per cent. of deaths, 56.

The board decided to have sputum examined by the bacteriologist in cases of suspected tuberculosis of the lungs, and circulars to that effect were sent to the physicians of the city. It was not with the idea of isolating the cases, although according to the latest accepted theory consumption is a contagious disease, but simply as an assistance to the physician in making his diagnosis.

The board of health believes, as stated in its annual reports, that a modern filter plant of suitable capacity should be constructed as an auxiliary to the present provision for Lowell's water supply. Such a plant is not expensive as compared with other measures to secure pure water. Its use in Lowell has already been advised by the sanitary authorities of the State, and its efficiency in preventing typhoid fever has been amply demonstrated. This board feels impelled to urge the immediate provision of the people of Lowell with this final safeguard against the enemy that has already wrought so much danger here.

LYNN.

By a suggestion from the local board of health, the city authorities ordered all dogs running at large to be muzzled from February 18 to June 1, 1896.

The board also secured the enactment of a statute providing for the filling of low land up to an established grade in the city of Lynn, whenever required by the board.

The following rule, known as rule 35 of the revised regulations of the board of health of the city of Lynn, was adopted, after approval by city solicitor Hon. John R. Baldwin, and after a public hearing given March 30. The purpose of the act was to keep out and prevent the sale of milk drawn

from unhealthy cows. Under this order 3,471 cows have been tested with tuberculin in the three States of Massachusetts, New Hampshire and Maine, and of this number 562 were condemned.

RULE 35. On and after May 1, 1896, for all milk brought into or offered for sale in the city of Lynn, satisfactory evidence will be required of the producer and dealer by the board of health that the milk has been drawn from healthy cows. The condition of health is to be based upon results of tuberculin test by a veterinarian that is satisfactory to the State Cattle Commission and to the inspector of milk for the city of Lynn. After test, each animal to have ear tag and certificate of health. Also, that the animals used are properly fed, and the premises occupied by them are in a good condition of sanitation.

Hospital for Contagious Diseases. — The condition of the hospital for contagious diseases the past year has been very satisfactory. It has been the purpose, in the management of this institution, to treat, as economically as possible, those patients suffering from diphtheria or scarlet-fever, who would have no other care or shelter without it, and to prevent the spread of these troubles, and we believe in the last year the institution, with the liberal use of antitoxin, has been the means of preventing a much larger number of cases and a much larger death-rate. A large proportion of these cases has come from those districts where the sanitary conditions are poor, and among those people whose families are large, and who are not accustomed to cleanly habits. For these reasons we believe that the hospital is a department working good in the city. The large number of cases of this kind reported shows how closely we may have come to an epidemic, such as has occurred in our neighboring towns and cities, where no provision has been made for their isolation. In the light of these events it seems a wise foresight on the part of our city in establishing this institution. Of the 82 cases of diphtheria admitted and treated there were 6 deaths, making a mortality of 7.32 per cent., while the mortality in the whole number reported in the city was 14.55 per cent., - about twice the death-rate of that at the hospital.

It is quite a practice in families where a contagious disease occurs for the parents to send the apparently well members away until the sick patient recovers. This course may seem proper and reasonable to a parent in his anxiety for the health and safety of his children, but it is a doubtful expedient, as it was found upon an inspection of cases reported that the patient was only stopping there temporarily, having been sent away from home to escape the disease. In one instance there were several cases reported from the immediate neighborhood of this temporary resident.

The following extract is from the report of the milk inspector: "For some reason other than a popular demand the practice of adulterating and diluting milk continues. This practice was attributable, during at least nine months of the year, to the annual destructive 'milk war.' Certain

dealers conceived the idea of cheapening the cost of milk to consumers, and it is safe to say they were successful beyond their expectations. During a part of this time milk sold as low as three cents per quart at retail. The quality of the milk was naturally affected, and as a consequence thirty-three dealers were brought into court; thirty-one fined and two discharged. During the year I have seized and caused to be analyzed 3,019 samples of milk and 103 samples of cream; of these 2,015 have been above the standard required. As one great source of the pollution of milk is the unclean cans, and ill-kept rooms where milk is put up, I have made sixty-three visits to these places, with the view, if necessary, of correcting such conditions as seemed detrimental to health."

MALDEN.

The gratifying results which have accompanied the antitoxin treatment of diphtheria has robbed this disease of a certain percentage of its horror. The reduction in price of this human boon, coupled with the fact that the board has freely furnished it upon request in all needy cases, has reduced the death-rate in our city of this most dreaded of maladies. At this point the board would endeavor to indelibly impress upon your honorable body the great existing need of a contagious ward or hospital.

In January the State Cattle Commissioners issued order No. 11, requiring that all dogs within a specified territory be muzzled for ninety days. The boards of health of the several cities and towns embodied in said order were authorized to see that the order was duly enforced in their respective territories. The city of Malden being included in this order, the board of health, to the best of their ability, enforced the order for ninety days from Jan. 23, 1896.

Regular medical inspection of the schools has been advisedly recommended, and the results have been very gratifying in those cities where it has been adopted. The board would recommend the same precautionary measures for Malden, and that an appropriation be made for the purpose.

Marblehead.

There has been no serious epidemic of any of the contagious diseases. The number of cases of diphtheria has been about the same as last year, but the mortality is not so great. This, in the opinion of the board, is due to the fact that in most cases antitoxin was used. We have, through the State Board of Health, furnished antitoxin free to every one desiring it.

MARLBOROUGH.

The quarantine in cases of diphtheria has been continued this year only when the throat cultures showed presence of the diphtheria bacilli. The board has adopted the plan of releasing patients from quarantine when a

throat culture was found free from the germs of this disease. This rule seems to the board to be a reasonable requirement, but the practical enforcement of such a regulation is often a hardship to the patient and family afflicted. In two cases which were quarantined during the year the germs remained in the throat for about ten weeks. As diphtheria patients are sometimes very much longer than ten weeks in getting rid of all diphtheria germs in the throat, and as the experience of the year is quite likely to be repeated, the necessity of providing an ample place for caring for this disease immediately suggests itself.

As our population increases the need of a systematic method of garbage collection becomes more apparent. The work of collecting swill and garbage is now being done by citizens, who register in the office of the board of health and agree to conform to the rules and regulations of the board in this respect; and although the swill is of some value to them, it is not enough to induce them to collect it in a systematic manner, for they generally go to the places where they can get the most and the best with the least possible trouble; so there are a great many places that are not visited, because, to use the words of the collectors, there is not enough to pay for the trouble. This matter can never be settled satisfactorily until the city makes an appropriation for the purpose of employing some one who shall gather swill and garbage in the city, and shall be under the direction of the board of health.

MEDFIELD.

Your board has acted on all complaints of nuisances existing in our town, and has remedied the same as they have deemed best. We have also taken such means and measures to prevent the spread of contagious diseases as in our judgment was proper. In combating the spread of infectious diseases, we have been obliged, in two instances, to remove the families from their dwellings while their apartments were being disinfected. In one instance we considered it best to remove the patients from their houses, as each recovered, to a temporary convalescent hospital, which we maintained for a period of two weeks for their benefit. We have allowed the town to bear the expense of maintaining this hospital, and also the cost of the board and lodging of the other family while this board kept them out of their home.

MEDFORD.

The work of the board has been materially increased during the past year by placing in its charge the inspector of plumbing, connecting with sewers, and the ordinance passed by the Cattle Commissioners, Jan. 23, 1896, requiring the muzzling of dogs.

At the close of the year a circular was sent to physicians who had reported cases of diphtheria to the board during the year, eliciting the following information: Eighty-two cases were reported. From 55 of these

cases cultures were taken and sent to Tufts or Harvard medical school laboratories, or to the State Board for bacteriological examination. Diphtheria bacillus was present in 45 cases; in 10 no diphtheria bacillus was present. Antitoxin was used in 59 cases. Deaths followed in but 3 cases where antitoxin was used. Arrangements have been perfected with the State Board of Health whereby microscopical examinations can be made.

MELROSE.

The correctness of the reports of contagious diseases is somewhat marred by the concealment of cases of sickness with the milder forms, as measles and scarlatina. This comes, perhaps, from a reluctance to have the card posted upon the house, and persons sometimes think they are sheltered by not employing any physician. But this is no excuse. The law says clearly: "When a house-holder knows that a person within his house is sick with . . . any contagious disease . . . he shall immediately give notice to the board of health. . . . Any person neglecting to comply . . . shall be punished by a fine not exceeding one hundred dollars."

The board has endeavored to have the sewer utilized as promptly as possible by the people, and therefore has followed up the progress of the sewer by a house-to-house distribution of circulars, stating the advantages of speedy connection with the sewer, and urging early action.

MIDDLEBOROUGH.

There has been no serious outbreak of disease in this town during the year. In January, a case of diphtheria was reported to the board, which, upon investigation, we were satisfied was contracted in Boston.

The board firmly believes that the time has come when the authority vested in local boards by the statute of 1891 should be enforced in this village, and the owners on the line of the sewer be compelled to enter, until not a privy, vault or cesspool can be found along any street where a sewer has been laid.

The attention to the use of the street as a dumping ground for paper and other articles too numerous to mention is asked.

MILLBURY.

For the immediate protection of the citizens of the town the board has arranged to have pathological examination made, at the expense of the town, from cultures from the throat when diphtheria is suspected. Test tubes and swabs can be found at the drug stores of the town, and antitoxin will be furnished free by the State Board on application at the office of the Worcester board of health.

NEWTON.

The board complied with the order of the Cattle Commissioners and instructed the police to seize all unmuzzled dogs, confine them at the nearest station and report to headquarters. A man was then employed to visit the stations daily and take the captured animals to the pound, which was established at the city farm. One hundred and thirty-six dogs were captured by this method during the period of ninety days, of which seven were shot and the remainder returned to their owners upon compliance with the order of the Commissioners.

A new rule requiring live fowl to be restrained upon the premises of the owner or keeper was adopted by the board during the year, and will undoubtedly render our streets more sightly by removing all manner of live fowl from them. The keeping of swine in a rapidly growing suburban city is not favored by the board, and only under the most favorable circumstances will it be allowed.

The bacteriological examination of cultures from suspected throats as an aid to the diagnosis of diphtheria has been continued during the year and has been of great service to physicians. These examinations are made free of charge to the patients, and the practice will be continued during the coming year, but under slightly changed conditions. The type of the disease has been fully as severe during the past as during previous years; many very severe cases having been in the contagious wards of the Newton Hospital. Many of the deaths have occurred in cases where there was some delay in administering the antitoxin, owing to the fact that a physician was not called until the patient had been ill for two or three days. The board strongly urges the advisability of the early administration of antitoxin.

The board last year referred to the need of a detention ward, where suspected cases of disease, notably diphtheria and scarlet-fever, could be held under observation if necessary, and it again draws attention to this need. Such a ward would be very valuable in a case of suspected diphtheria, say, occurring in a domestic in a family where there are young children.

NORTH ADAMS.

Two hundred and eighty-one official notices have been served. Ten cases have been prosecuted for not obeying orders of the board.

The Notch water-shed is very small, comprising only two farms and one or two "wood-lots." The slope on either side of the stream is steep, and the buildings dangerously near the water. As the city was building a large reservoir on this stream the board considered it advisable that it purchase the farms, remove all the buildings and allow the whole water-shed to grow up to timber. Acting on this belief it conferred with the State Board of Health, and its opinion being confirmed the matter was laid before the

mayor, and upon his recommendation the purchase of the two farms was made.

The board would call attention to the necessity of a hospital for contagious diseases.

NORTH ATTLEBOROUGH.

We feel that there would be much less friction, and more certainty of maintaining good sanitary conditions throughout the town, if the town had seen fit to authorize a yearly examination of all tenements, as well as public buildings, under the direction of the board.

There is one by-law of the town that is constantly disregarded by the people of the town, and especially in the business part of the town. We refer to the strewing of paper, etc., around the streets.

During the past year the State Board of Health has provided for the examination of the discharges from the throats of those suspected of being affected with diphtheria; and also of the sputa of any cases of suspected tuberculosis. We are unable to state how many cultures have been made and forwarded to Boston for bacteriological examination, as those availing themselves of this privilege have failed to make a report to us. The value of these examinations was well illustrated in one case, by report returned that no evidence of diphtheria could be found. The physician in this case showed his good judgment by isolating the family until his doubt in the case was removed by the report of the examination of the discharge from the throat. Thus, without further delay, the family were relieved from the hardships attendant upon quarantine.

The State provides antitoxin for the use of towns, requesting, in return for such favor, that detailed records of the cases where it has been used should be kept and forwarded to the State Board. Wherever the antitoxin has been used in the early stage of the disease the result has been most satisfactory. Out of twelve reported cases only two have proved fatal. In one of the fatal cases the child was not seen until it was almost moribund; in the other case, death was due to paralysis of the heart, the membrane having entirely disappeared.

Norwood.

Swine in the centres of population are regarded by the board of health as a nuisance.

The sanitary arrangements of public buildings in which large numbers of people are housed should be in harmony with modern developments. This is never more true than in the matter of school-houses.

The board of health, in the interest of common humanity, would ask every one to refrain from expectorating in any public building or conveyance except into receptacles provided for the purpose.

ORANGE.

The amount of sickness has been far less than usual. Contagious and infectious diseases have been unknown; the death-rate has been 10 per cent. less than an average.

QUINCY.

The general health of the city has been very good, no serious epidemic of contagious disease prevailing, nearly all the cases that have occurred being of a mild type, yielding readily to medical treatment. The danger from diphtheria, that dreaded disease, has now by the use of antitoxin been greatly lessened, and the death-rate lowered.

The board unanimously recommends that a more efficient service for the collection of the garbage of the city be maintained. By so doing it will be of great benefit to all, and the cleanliness and health of the city much improved.

Personal visits and inspections of all the public buildings, school-houses, etc., have been made by the members, and defects and nuisances been remedied.

PITTSFIELD.

One practice in our schools is without doubt a fruitful method of transmitting infection. We refer to the method of collecting pencils used by pupils during the day and passing them out indiscriminately the following day. We trust that the school authorities will order this practice permanently discontinued, as pernicious in its effects. When a pupil is reported as sick with scarlet-fever or diphtheria the books used by such pupil should at once be burned. It is to be regretted that one school building should be made the store-house for all the old books from all other schools in the city. These old books, as soon as unfit for use, should be destroyed at once. The general drinking cup should be a thing of the past, as it is a source of danger. Each child should have a cup of his own, as is the case in many schools.

PLYMOUTH.

During the months of April and May an inspection of the town was made, and the contents of sixty-eight cesspools and privy vaults were ordered removed. A number of complaints have been made, all of which have been investigated. Eight houses have been connected with the sewer, by order of the board.

PROVINCETOWN.

Every year our town seems to be becoming more popular as a summer resort, and we ought to co-operate in making our shores not only clean, but just as attractive as possible. Let us place no obstruction in the way of the summer guest enjoying our shore privileges. We would recommend that measures be taken to do away with shore sewerage, also all promiscuous dumping of fish from wharves, etc.

REVERE.

The work of connecting houses with the public sewers has been vigorously kept up, and we trust that old-fashioned vaults and illy-kept cesspools will soon cease to be a menace to the health of the community. Many desirable improvements have, of necessity, been postponed on the ground of rigid economy. Less complaint has been made against our large piggeries than ever before. A sharp eye has been kept upon them, with a very gratifying improvement in their general condition, and the total abandonment of one large plant. The enforcement of the law in regard to plumbing is bringing about a sure change for the better in the quality of the work done, and an added safeguard against disease. The plumbers, with slight exception, have cheerfully complied with the requirements of the board, and only in one instance has our authority been openly defied. The inspection has been thorough, and accomplished in a first-class manner.

SALEM.

The board has encouraged the use of antitoxin in all cases, and adopted the policy of furnishing it whenever there was danger that otherwise it would not be used. Practically, this resulted in the furnishing of the remedy by the board for nearly every case. It was not possible to make a correct record of the number of cases in which antitoxin was used, as complete reports could not be obtained from all physicians, but it was used in a very large majority of the cases.

SHARON.

The favorable health conditions that have prevailed in the town during the year have required but little service from the board.

SOMERVILLE.

The number of loads of ashes collected during the year was 19,240.

The house offal has been collected by the city during the year under the same system that has been employed in the removal of ashes.

The collection of night-soil during the year has been very small, as the old-fashioned privy-vaults have been almost entirely removed.

SPRINGFIELD.

The health of the city has been, on the whole, good; we have had no serious epidemic of communicable diseases. Typhoid fever was reported 46 times, chiefly in May and August. In the latter part of May some 15 cases were discovered in ward 5 and the adjacent part of ward 8, which seemed to have a common origin. The patients had a common milk supply from a farm in a neighboring town. We found upon this farm a

young woman had lived during a portion of the month of May; that she had become ill and left the farm about May 23, and at the time of this investigation was suffering from typhoid fever. The use of this milk was forbidden until it was evident that there was no reason to fear further contamination and the epidemic ceased.

The use of the diphtheria antitoxin, which was unusual at the beginning of the year, is now common and results in saving many lives. Forty-five cases received this treatment and 5 of them died, while of the 48 cases treated in other ways, 21 died. But in 3 of the 5 fatal cases the antitoxin was used when the patient was already near death, so that in those cases where the antitoxin was properly used only 4.4 per cent. died, while 47 per cent. of the others perished. That is, cases treated by antitoxin did ten times as well as cases not so treated.

TAUNTON.

No alarming epidemic has occurred, although the three important contagious diseases, diphtheria, scarlet-fever and measles, have been present in the city to some extent almost continuously throughout the year.

Diphtheria was decidedly less than the previous year, and at no time was the disease especially confined to one locality to any marked degree. The board has continued to distribute antitoxin gratis to the physicians, which has been, as also during the previous year, furnished to us at no expense by the State Board of Health. In November the board took advantage of the offer of the State Board to make free cultures for the Klebs-Loeffler bacillus of diphtheria. Stations where the culture tubes may be obtained have been established. This offer of the State Board in regard to antitoxin and culture examination applies equally to the adjacent small towns for which our board is headquarters.

The number of nuisances reported at this office and entered in the nuisance record book for the year has been 227, an increase of 30 over the preceding year. The majority of the complaints have been for overflowing or foul privy vaults, sink drains, cesspools, garbage heaps and foul catch-basins. The routine pursued by the board in cases of nuisances has been for the agent to visit the premises where the alleged nuisance exists; if the nuisance is real the proper person is notified verbally or by written notice to abate the nuisance within a reasonable time specified. If at the end of that time no steps have been taken towards abatement, legal notice is served upon the party, requiring him to abate the nuisance under penalty of the law. A continued negligence to abate is followed by a complaint lodged with the police department summoning the person into court. The greatest nuisance of all, and one over which the board appears to be powerless, is Mill River. During the summer months the complaints from this source were constant and unceasing. This vast sink-drain, receiving

the contents of numerous privies, sinks, cesspools, sewers and other containers of filth, during the hot weather is a source of the greatest annoyance to the unfortunate residents along its banks, many of whom it must be confessed add their little or large share, as it may be, to the already undue amount of foul deposit in the stream.

TEWKSBURY.

A child, aged three years and seven months, was taken ill with diphtheria, being the first to show the disease, and had the croupous form, requiring intubation, the tube remaining in the larynx four days. She made a full recovery. The remaining cases were subjected to the treatment as soon as the disease appeared, and though they had the disease in a severe form, all made full and perfect recoveries, which I believe was largely due to the antitoxin treatment used, and skilled nursing.

WALTHAM.

It has been the policy of this board to maintain the standard of work so admirably set forth by its predecessors in regard to the sanitation of the city, realizing that eternal vigilance is the price of municipal health, and that the application of the best and latest scientific methods are essential to the physical well-being of any community.

We have strenuously insisted, as far as possible, on the connection of all buildings with the sewer system, when such buildings lie upon the route of sewer pipes.

Diphtheria. — There were 75 cases, with 5 deaths; 34 of the cases were removed to the Waltham Hospital for isolation, and this was done, if possible, in every case where the proper quarantine regulations could not be carried out at the patient's home. To prevent cases being freed from quarantine too soon for safety to others, the board added to its rules one which requires that two negative bacteriological results must be obtained, three days apart, before the restrictions of the quarantine can be removed.

WARE.

Diphtheria antitoxin is in general use by physicians here who have the care of diphtheria cases. The results following its use have been very good, and families generally are now willing to have its use made.

WARREN.

Scarlet-fever has been so mild that parents, in a few cases, have not recognized it, or no attention has been given to it, and consequently children have been allowed to mingle with the public; even attend school. One unrecognized case makes mischief, and to a great extent these un-

recognized cases have been the cause of the continued epidemic of this disease during the past three years.

The board of health has obtained from the State Board of Health the establishment of a station where all physicians can procure culture tubes, to be used where diphtheria is suspected, also diphtheria antitoxin for the treatment of this disease.

Fifty-six children were vaccinated, as a part of the work of the board, this year.

WATERTOWN.

Rules governing the use of the bath-house were adopted, and the work has been conducted satisfactorily since that time, giving apparent satisfaction to the people.

A slaughter-house has been a source of annoyance and trouble to the boards of health for several years. The proprietor was given every reasonable opportunity to keep his place in a presentable condition, and to obey the provisions of the law as he knew them. It was only after repeated complaints of violation of the law that it became necessary to take the extreme measure which was resorted to. It is very unfortunate that a man should be deprived of earning a livelihood such as he selects for himself, but it is much more important that he should have no opportunity to spread contagion and disease among people by the slaughter of tuberculous animals, and the opportunity to put such food into the market.

Many complaints were made about the keeping of large numbers of swine within the town limits, although outside of the scope of the rule formerly established by the board of health. On May 29, 1896, the rule was changed so that now no swine can be kept in any part of the town without a license from the board of health. The result has been a gradual diminution in the number of swine kept in close proximity to rapidly growing localities outside of the former one-mile limit where licenses were not required.

It has been demonstrated by thousands of cases that the early administration of antitoxin will cure nearly every case of diphtheria. The point that the board wishes to emphasize is that it should be injected in the beginning of the disease, and that parents should hasten to report cases of sore throat to their physicians. The State Board of Health manufactures antitoxin in its own laboratories, and furnishes it free of cost to any physician. A supply of this remedy, obtained from the State Board, is always kept on hand by our board, and will be furnished to any physician who applies to the agent.

Many patients have been known to have the germ in the throat long after all other symptoms have disappeared. Such a person is still capable of spreading the disease, and should not be allowed to attend school until the culture is found to no longer contain the typical germ. Impressed

with the importance of this precaution, the board voted that no person sick with diphtheria should be considered recovered until a negative culture was found. The State Board of Health makes these cultures free of cost, and furnishes the proper boxes for taking the culture.

WESTFIELD.

We make a much more favorable report of the general sanitary condition of the town than in our last. Our mortality record is considerably lighter, and the decrease in cases of contagious and infectious diseases most encouraging.

We believe the town is beginning to reap a rich reward for the money expended in her grand water supply, extending the public sewers, surface drainage, collection and removal of garbage by our sanitary cart, and other thorough improvements which are being made.

Copies of the act of 1896, chapter 418, have been posted in each of our bakeries, as required by the act, and a compliance with its requirements insisted upon, as far as could be done, in the buildings now occupied. The improvements are quite satisfactory.

WHITMAN.

The past year has been prolific of work in the line of nuisances complained of, and sanitary irregularities to remedy. One hundred and seven complaints reported and attended to, against seventy-three last year. Thirty-nine quarantine cards posted, against thirty-six last year.

WINCHESTER.

It having been brought to our notice that owners of property, on streets where the public sewer had been completed, were slow to avail themselves of the privilege of making house connections with the same, the board issued to property owners on those streets in which the sewer was laid in 1894 the following notice:—

You are hereby notified that the public sewer on the street upon which your estate abuts is completed, and that your buildings should be connected with said sewer, by a good and sufficient drain, immediately.

Connection will be made for you at a price not exceeding the cost of labor and material, by the sewer commissioners, on application filed with them.

You are respectfully requested to file your application within sixty days.

To this notice or circular was attached a copy of the act, chapter 132 of laws of 1890, entitled "An Act to provide for connecting buildings with public sewers."

Contagious diseases have been largely in excess of last year, and diphtheria, particularly, has given us much trouble and anxiety. It is due, we

think, to the fact that parents, when there is a case of diphtheria in the family, will not strictly confine their other children to their own premises.

We have had quite a run of malarial fever, and the laying of our new sewer is, by many, thought to be the cause. This, however, cannot be the fact. There is no reason why the digging up of our streets, when the soil is mostly sand, should generate or liberate malarial germs.

WOBURN.

With the advent of the sewers there is a decided improvement in the drainage of the city.

The number of cases of diphtheria for the past year was eighty-six, two of which were fatal.

During the year the board undertook and carried out the work of cleaning out Horn Pond, a large pond of about one hundred acres, into which the drainage of tanneries had been discharged for many years, and which had become offensive in consequence of the growth of large quantities of foul-smelling algæ.

WORCESTER.

Public baths have been repeatedly recommended in our annual reports, and it is a matter of gratification to this department that the establishment of the same is apparently near realization. Regatta Point, if it can be procured, is probably the best spot for location, but if it cannot be had there should be no difficulty in obtaining permission from the parks commission to locate on a part of the Lake Park.

Bacteriological Department.— The work of this department during the year has been satisfactory, and continues to justify its establishment. In several cases where death has been sudden, and suspicions of diphtheria aroused, we have been able, through its aid, by cultures made after death, to fix the disease positively, and thus fortified have taken the necessary precautions to prevent its further spread. Nine hundred and forty-seven cultures in all were examined during the year.

All the known bakeries of the city have been inspected and a copy of the act posted in each. Orders have been issued to make the alterations found necessary.

In August last a report was received of three cases upon the route of a milkman who lived in a neighboring town, and a visit was paid to his honse, where he was found sick in bed suffering with what was said to be "malarial fever." A call by telephone the next morning upon the physician in attendance disclosed the fact that it was typhoid. It was also found that there was a case of it in the family of the man from whom the milk peddler received more than half his whole supply. He kept no cows himself, buying all of the milk from neighboring farmers. Prompt measures were taken to prevent any further spread of the disease from this source. In all, eight cases were reported, with two deaths, among families

who received their milk from this peddler. All of these cases had their beginning about the same time. No new cases were reported whose symptoms began subsequent to the precautions taken by this department, as was mentioned above.

The Isolation Hospital, for the treatment of patients suffering with diphtheria and scarlet-fever, was completed during the year. It was opened for the reception of patients November 25. The cottage or separate pavilion plan was the one selected by the board of health, and consists of four separate buildings, arranged somewhat in the form of a hollow square.

The following rules have been adopted by the board for the regulation of the hospital:—

- 1. Patients may be admitted to the privileges of the hospital by the board of health, at such rates of board as it may from time to time determine.
- 2. In all cases where, in the opinion of the board, the circumstances of the patient will warrant it, the whole or a part of the board shall be paid.
- 3. Patients admitted to the Isolation Hospital cannot receive visits from friends, unless such patients are dangerously ill.
- 4. Inquiries concerning such patients may be made at the office of the board of health, or by telephone at the hospital.
- 5. If a patient should become dangerously ill, the nearest relative or friend will be notified, with an intimation that he may be visited. Except in very urgent cases only one visitor will be allowed.
 - 6. Visitors are advised:
 - a. Not to enter any of the wards when in a weak state of health or in an exhausted condition.
 - b. To partake of food before entering the hospital.
 - c. To avoid touching the patient or exposing themselves to his breath or to the emanations from his skin.
 - d. To sit on a chair at the bed-side at some little distance from the patient, and not to handle the bed-clothes.
- 7. Visitors will be required to wear a gown, which will be provided at the hospital, to cover their dress when in the wards, and to wash their hands and face with a disinfecting solution.
- 8. Each visit must be limited in time, and friends must leave when requested by the resident physician or the nurse in charge.
- 9. No visitor shall be allowed to give any article of food or drink to a patient unless by permission of the nurse.
- 10. No visitor will be allowed to take any meal in the hospital, or to pass the night therein, without permission from the board of health or the resident physician.
 - 11. When the patient ceases to be dangerously ill friends cannot be admitted.
- 12. Religious services for the dead may be held in the chapel. The attendance is strictly limited to the officiating clergyman and the adult members of the immediate family.
- 13. Visitors are strongly urged not to enter any street car or other public conveyance immediately after leaving the hospital.

NOTE.

The following information should have been inserted on page 682, at the close of the two years' summary of the use of antitoxin, but was received too late for insertion at that point:—

Use of Antitoxin for Immunisation.

Antitoxin, furnished by the State Board of Health, was employed at the Children's Hospital, for the purpose of immunisation, as follows:—

| During the During the | - | - | | | | 678 patients 511 patients |
|--------------------------|---|---|--|--|--|------------------------------|
| Total, | | | | | | 1,189 patients |

No record was kept with reference to complications or sequelæ in these cases, but a note from the superintendent states that "urticaria occurred in only a small number of cases and these were not particularly noteworthy."

In three cases only did diphtheria develop after injection of antitoxin for immunisation, in one case in 36 days and in two cases in 23 days.

There was occasionally "some tenderness for twenty-four hours at the seat of injection, but it soon passed off."
